INDEX TO VOLUME II FOR 1929.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, *X* Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

Abbey of Orval (J. Tricot-Royer), 928
ABBOTT, G. H.:—Address as President of the Australasian Medical Congress: Progress made in the treatment of disease in the last forty years, 921

EPITOME

OF

Current Medical Literature.

JULY TO DECEMBER, 1929.

F. W. W. GRIFFIN, M.D.,
SUB-EDITOR.

London:
PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME II, 1929.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

Abdominal incision, a modified, 267
Abdominal symptoms due to enlargement of the mesenteric glands, 384
ABELOUS, J.-E.: Asthenia following suprarenal destruction, 453
Abortus fever in Denmark, 258
Abscess of lung, carcinomatous, 210
Abscess of lung: Etiology of, 230—Treatment of, 484
Abscess, subphrenic, 310
[illegible]
Acid-fast bacteria. *See* Bacteria
Acid treatment of hay fever, 292
Acriflavine in undulant fever, 315
ADAMSKI, J.: An agar method for the isolation of water spirochaetes, 178
Addison's disease, suprarenal cortical extract in, 243
Adenitis, tuberculous, of the cheek, 61
Adenocarcinoma of the uterus, 350
Adiposity following suppression of catamenia, 136
Adrenaline: Action of after sympathectomy, 41—Intravenous injections of in cardio-vascular collapse, 168
ANSON, A. W.: Surgical treatment of Raynaud's disease, 29
Agar method for the isolation of water spirochaetes, 178
Agranulocytosis: With recovery, 236 — And influenza, 284—In diphtheria, 428
Alastrim, the nature of, 569
Alcohol injections in trophic ulcers, 35
Alcoholic pseudo-pellagra, 460
ALDERSHOFF, H.: The nature of alastrim, 569
Alkali load as a test of the kidney function, 133
Alkalization test of renal function, 454
ALLEN, M. S: Relation of bacteria to chemically induced pneumonia, 280
Allergic conditions, therapeutic agents in, 144
Allergic intestinal diseases, sodium ricinoleate in, 578
Allergy, typhoid, 304
ALVIN, J. V.: The ocular signs of general paralysis, 91
Amaurosis in epidemic encephalitis, 148
Amaurotic family idiocy in Japanese families, 346
Amoebic dysentery. *See* Dysentery
Amyloid degeneration, experimental, 132
Anaemia due to gastric deficiencies, 306
Anaemia, Lederer's, 331
Anaemia, pernicious, desiccated stomach in the treatment of, 557, 558
Anaemia, pernicious, insulin in, 366
Anaemia [illegible] of, 63,
[illegible]
compounds, 43
Anaesthesia, ethylene, 236, 297
Anaesthesia, general, precautionary methods in, 170
Anaesthesia for head operations, 42
Anaesthesia, local, in first and second stage labour, 219
Anaesthesia, nitrous oxide-oxygen for goitre
[illegible]
thalmic goitre, 445
Anaesthesia, spinal, volume control of, 298
Anaesthetic, a new local (perkain), 465
Anaesthetic of diminished toxicity (cyclopropane), 417
Anaesthetics, influence of on the blood volume, 446
Anaphylaxis, effect of on the course of infection, 176
Anaphylaxis, ocular, 345
ANDERSON, K. W: Diabetes mellitus and arterio-sclerosis, 328
Aneurysm, traumatic subclavian arterio-venous, 464
Angina, coronary, acute febrile, 203
Angina pectoris, surgical treatment of, 188
Aniline dyes. *See* Dyes
Ankle, fractures at the, 462
Antimony in schistosomiasis, 512
Antirachitic medication, dangers in, 520
Antitoxin, scarlatinal, immunization against scarlet fever by, 286
Antitoxins, origin of, 498
Aortitis, syphilitic, malarial therapy in, 511
APERT, E: Sex factors in influenza, 103
Aplasia of the gall-bladder, 362
APOSTOLON, G.: Sodium cacodylate in malaria, 342
Appendicectomy, difficulties in, 62
Appendicitis and pyelitis, concurrent, complicating pregnancy, 45
Appendicitis and tonsillitis, 269
Appendicitis in typhoid fever, 465
ARCHIBALD, E.: Surgical treatment of pulmonary tuberculosis, 437
ARISTOWSKY, W. M.: Immunization against relapsing fever, 461
Arsenical therapy in syphilis, 412
Arsenobenzol therapy in Vincent's stomatitis, 293
ARSONNEAU, P.: Filterable forms of typhoid bacilli, 261
Arterio-sclerosis and diabetes mellitus, 328
Arterio-sclerotic Parkinsonism, 89
Arterio-venous aneurysm. *See* Aneurysm
Artery, external pudic, thrombosis of in chicken-pox, 508
Artery, hypogastric, sympathectomy of, 566
Arthritis, gonococcal vertebral, 430
Arthritis of hip-joint in enteric fever, 238
Arthritis, tuberculous, multiple, 576
Asphyxiated newborn, resuscitation of the, 323
Aspiration during tonsillectomy, prevention of, 386
Asthenia following suprarenal destruction, 453
Asthma, bronchial, 329
Asthma: Modern remedies for, 36—The nose and throat in, 216—Therapeutic vasotrophic shock in, 341—Toxicosis in, 573
Asthmatic attack, etiology of the, 79
Atrophic rhinitis treated by radium, 538
AUBERT, M.: Undulant fever, 1
AUBREY, E.: General paralysis of the insane, 274
Auricular fibrillation, quinidine sulphate in, 190—Ventricular rate in, 227
Autohaemotherapy in nephritis, 9 — In gastric ulcer, 247
Avian pollution of drinking water, 476
Avertin anaesthesia. *See* Anaesthesia
AVERY, R. C.: Differentiation of haemolytic streptococci, 456

B.

BAASTAD, F.: Schlatter's disease and allied conditions, 409
BABALIAN: Ergotamine tartrate in urticaria, 244
Bacilli, *proteus*, the swarming of, 155
Bacilli of the salmonella group, precipitable
[illegible] .o, 513
B.C.G. inoculation, prophylaxis by, 551—Tuberculin reaction after vaccination with, 580
Bacillus, Ducrey's, saprophytism of, 358
Bacillus faecalis alkaligenes as a cause of pyrexia, 522
BACON, D. K.: Hyperthyroidism as a cause of cardiac disability, 547
Bacteria, acid-fast, influence of iron on the pigmentation of, 354
Bacteria, relation of to chemically induced pneumonia, 280
Bacteriaemia, post-operative, in malignant growths, 546
Bactericidal action of tuberculous serum, 326
Bacterial resistance to the bacteriophage, nature of, 202
Bacteriophage phenomena, 50—Nature of bacterial resistance to, 202—Treatment of cystitis, 467
BADER, G. B: Prophylaxis against measles, 431
BAILLAT: Indications for myomectomy, 395

'CHARKAOLIN'

GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

The BRITISH JOURNAL of UROLOGY.

Edited by

FRANK KIDD, M.Ch., F.R.C.S., and H. P. WINSBURY WHITE, F.R.C.S.

SECOND NUMBER *JUNE* *NOW READY*

Quarterly 6/- net. Annual Subscription 20/- (post free).

The first and the only English periodical devoted exclusively to the consideration and advancement of this ever-increasing and important branch of Medical and Surgical Science, and issued under the auspices of an Editorial Committee, the members of which are noted for their interest in urological work, both in the United Kingdom and in the British Dominions overseas. The Committee confidently appeals to all who are interested, including the General Practitioner, whose interests have not been overlooked, to support the Journal by becoming regular Subscribers and sending their orders at once.

CONTENTS

Editorial Notes
Editorial Notices
Notices of Urological Meetings and Post-Graduate Courses

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

WESTMINSTER BANK LIMITED

HEAD OFFICE: 41 LOTHBURY, LONDON, E.C.2

Have a B & P Motor House

THE FRENCH NATURAL MINERAL WATER

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins**, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,
Bangor Wharf, 45, Belvedere Road - - - - - - - London, S.E.1
And at LIVERPOOL and BRISTOL.

"THERE WAS GENERAL IMPROVEMENT IN HEALTH IN A FEW DAYS."

(4D) "I have prescribed Bemax for patients suffering with debility after influenza. There was general improvement in health in a few days." M.B., B.S.

(5D) "I take Bemax myself and have continued to take it as I find it so beneficial. I take it with porridge and milk. When I began taking Bemax the effect was noted in a few days. I felt better and stronger, and better able to bear fatigue. I have much pleasure in recommending it to my patients and I have had pleasing results."

Bemax is now established as the B vitamin food. Over 27,000 members of the medical profession are taking Bemax themselves or prescribing it for their patients, with excellent results. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxæmia, Debility, Neurasthenia, Rheumatism, Gastric disturbances and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full-size tin will be sent you on receipt of your professional card.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Science once more endorses HOVIS

IRREFUTABLE EVIDENCE

Scientific Research into the essential factors underlying the bread question has brought to light certain facts of the highest practical value to medical men as well as to the general public.

HOVIS is shown, from an analysis of many experiments, not only to possess a larger content of the vital element Vitamin B than other breads, but provides more positive nourishment for the quantity consumed.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of wholemeal, or 5 to 6 g. of fresh yeast; white bread contains only about 2 per cent. of yeast.

It is also found that "brownness" of bread is no measure of the Vitamin content.

The Wheat Germ
the secret of Hovis Nutrition

By blending the finest white flour with 25 per cent. wheat germ, HOVIS combines the goodness of the one with the rich Vitamin B qualities of the other. Further, containing no bran, it is very easily digested.

These facts all point to one conclusion: that in dietetic value HOVIS holds the first place for promoting health.

Therapeusis in Pulmonary Tuberculosis

By increasing the calcium content of the blood the resistance of the whole organism against the bacterial toxins is greatly strengthened, there is a decrease in the excitability of the nerves, and a definite improvement in the functions of the alimentary canal, due to the combined anti-toxic and astringent effect of the calcium salts.

Successful calcium therapy depends upon calcium retention. The calcium-sodium-lactate compound, presented as a double salt in the form of Kalzana is easily absorbed and well retained. The sodium-lactate is changed within the body to sodium-carbonate, which raises the blood alkalinity to the extent necessary to secure calcium retention.

"The Practitioner," June, 1924, says:
"It is indicated in all conditions in which a lime food is required, particularly because Kalzana promotes calcium retention."

Kalzana is in daily use at over 200 British Sanatoria and Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

INSULIN "A.B."

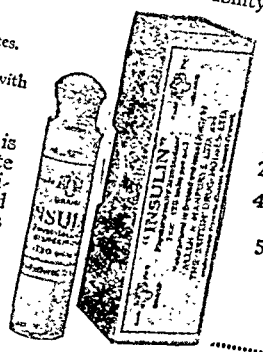
TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A diet of Mellin's Food

in conjunction with fresh cow's milk and water, produces an immediate gain in weight in fermentative dyspepsia and in the wasting disorders of early infancy.

As is well known, sugars exhibit varying tendencies to fermentation in the digestive organs—milk sugar ferments most rapidly, less rapidly cane sugar, and maltose still more slowly, and the high percentage of maltodextrin in Mellin's Food accounts for its usefulness in all such cases of malnutrition.

A NURSE on a private case has many difficulties to face. That is the reason a private nurse should always carry Marshall's Lysol in her bag.

For Marshall's Lysol is an antiseptic which is perfect for every conceivable use . . . which is used by the greatest hospitals in their war against infection and disease. Marshall's Lysol, therefore, is the Lysol on which a nurse can rely. Marshall's Lysol is the only Lysol made from the original formula. A doctor who recommends Marshall's Lysol KNOWS that his patients will obtain a lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease the highest grade antiseptic is absolutely essential.

In the treatment of

Asthma and Hay-Fever

EPHEDRINE B.D.H.

Attention has been directed recently to the value of ephedrine to the asthmatic, and to the physical and mental relief afforded to the patient who is aware of the availability of this drug. (*B.M.J.*, May 25, 1929, p. 954).

Ephedrine brings remarkable comfort also to those who suffer from hay-fever.

Ephedrine B.D.H. is the naturally-occurring lævo-rotatory alkaloid prepared from the Chinese plant, Ma Huang; it is separated from its isomeride, pseudo-ephedrine, and is carefully purified. The natural alkaloid has proved to be considerably more active physiologically than the synthetic product.

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND NEURASTHENIA

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology.

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

to the MEDICAL PROFESSION

SAVORY & MOORE'S
MAYFAIR "A" BRAND

NUSALIN

TRADE MARK

A perfectly balanced Effervescent Saline designed to correct all functional disorders and to assist the organs of the body, associated with elimination of waste matter from the blood and intestines.

NUSALIN is admirably suited to the needs of diabetic subjects, being

SUGAR FREE.

Its components are of the highest degree of purity, which render the product in graduated doses suitable alike for Children or Adults.

NUSALIN is non-habit-forming, and may be readily prescribed in cases of Chronic Constipation. It induces a normal condition of the bowel, and assists in *reducing the* atonic state too often arising from the continued use of strong cathartics.

NUSALIN is acceptable where a digestive corrective or liver stimulant is indicated. The Saline is of value in correcting the irregularities attendant upon Pregnancy. In cases of excessive acidity which may develop into Gout, Rheumatism, Sciatica, etc., the alkaline nature of the product will recommend its use.

NUSALIN is in form a dry free-flowing white powder, containing its laxative constituents in an effervescent medium.

Usual dose: From ½ to 2 teaspoonfuls added to a half-tumblerful of water, according to action required.

Telegrams: *"Genatosan, Loughborough."*

The best is cheapest

—that is an old phrase to which the makers of Robinson's Patent Barley have lent new truth and added weight

I. It is an astonishing fact that Robinson's Patent Barley at 1/3 per lb. is actually cheaper in use than ordinary barley at 2½*d.* to 4*d.* per lb.

Robinson's Patent Barley makes a pint of barley water for ·19*d.* whereas pearl barley makes the same amount for ·25*d.* or ·4*d.*

The paradox is explained by the comparative wastage. In making Robinson's Patent Barley there is none. In making barley water with pearl barley there is an average wastage of 87·5%!

II. And there are other economies. It takes little more than the time it takes to boil a kettle to make barley water with Robinson's Patent Barley—to make barley water with pearl barley needs an hour or more of patient stewing.

Robinson's Patent Barley saves waste of time and waste of fuel.

III. And withal Robinson's Patent Barley satisfies the most exacting tests of purity—the same cannot be said in all cases of pearl barley. Robinson's Patent Barley is cleaned and very finely ground under the most scrupulous conditions—it is packed in sealed hygienic tins.

The best is cheapest

KEEN ROBINSON & CO. LTD., CARROW WORKS, NORWICH

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

Vitamins

AND DRIED MILK

The vital importance of an adequate supply of vitamins in the feeding of infants is now well recognised, not only in the prevention of obvious deficiency diseases such as rickets and scurvy, but also in the maintenance of the general resistance against the common infections of the respiratory, alimentary, and urinary tracts, and the determination of a normal equilibrium between the various endocrine secretions.

The vitamin content of milk depends in the first instance on the character of the diet supplied to the cows. English pasturé-fed herds furnish a milk superior in its vitamin content to that of stall-fed animals or those fed on inferior pastures of dry and tropical climes. The Cow & Gate dairy farms and laboratories are situated in the rich pastures of Somerset and Dorset, and thus a high vitamin content of their milk is assured, obviating the necessity for the addition of synthetic vitamin concentrates which are very doubtful in their action.

The survival of the vitamins in the dried product depends on the process employed. The Cow & Gate Roller process of drying milk involves exposure to heat for a matter of seconds only, with the result that the vitamins are for all practical purposes intact.

There have been no proved cases of rickets where Cow & Gate Milk Food has been used. Many feeding experiments in the hands of well-known investigators have demonstrated that adequate nutrition and growth are assured on a diet of this food, which has now been widely recommended by the Medical Profession for over a quarter of a century.

The Manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

PALM-LEAF PAGE FROM THE MOST ANCIENT SANSKRIT MANUSCRIPT KNOWN.—The mother-tongue of the original Indo-European (Indo-Germanic) people gave rise to seven principal branches: Sanskrit, Iranic, Hellenic, Italic, Celtic, Teutonic, Letto-Slavic. Of these, Sanskrit has the distinction of being the only one still existing and of being still represented by actual literary documents. We do not know at what date the ancient Indians first began to commit their compositions to writing, but the oldest "book" so far discovered, a page of which is here reproduced, was by no means the first. The fragmentary condition of the present example makes a translation of its contents impossible, but it is clear that the pages contain portions of dramas. It is written in the early classical Sanskrit, which was the official literary language of the Indo-Aryan culture.

Some Observations ON DISEASES OF THE MYOCARDIUM.*

BY
R. O. MOON, M.D., F.R.C.P.,
CONSULTING PHYSICIAN, ROYAL WATERLOO HOSPITAL; PHYSICIAN, HOSPITAL FOR DISEASES OF THE HEART.

THE lecture which I have the honour of delivering this afternoon was founded by Lady St. Cyres. It was her intention that the subject of the lecture should be definitely connected with the myocardium, so I have decided to give you some account of the way in which the muscle of the heart becomes diseased, what are the manifestations of the morbid condition, and what may be the outlook, together with some suggestions as to treatment.

SOME HISTORICAL CONSIDERATIONS.

It must always seem a strange thing that the ancients should have been under the impression that of all the organs of the body the heart alone could not be diseased; and indeed remarkably little was known about the heart and the circulation generally until the publication of Harvey's great discovery in 1628. Even after that very little was known or written about diseases of the heart for more than a century. Until the discovery of percussion and auscultation by Auenbrugger and Laennec respectively there was almost complete ignorance of valvular disease, but after that so much attention was focused upon the lesions of the different valves that the importance of the myocardium was somewhat neglected. With the advent of the modern cardiology, however, this has all been changed, and for the last thirty years attention has been closely directed to the study of the myocardium.

As far back as 1534, prior to the advent of Vesalius, Nicholas Massa of Venice had observed hypertrophy of the heart muscle, but it was not till more than a century later that Morgagni (1682–1777) called attention to chronic myocarditis, which he regarded in some respects as a degeneration of the heart muscle. Corvisart, in his well-known book[1] upon the heart, lays considerable stress upon the importance of the myocardium; it is, he said, the muscular substance of the heart which most essentially constitutes the central organ of the circulation. He described the gross changes in the size and shape of the various chambers —for example, dilatation and hypertrophy. He was of opinion that a change of form or length of the fibres of the myocardium was visible proof of its disordered action, but apparently he did not realize that, though the myocardium might be fatally weak, it yet might present to the naked eye no change in the general form, nor did he lay much stress upon inflammatory or degenerative conditions of the myocardium, though he seems to have been the first to make use of the term "carditis."

The pupil of Corvisart, the famous Laennec, who first introduced auscultation in 1819, spoke of the condition of the myocardium as "the key to cardiac pathology." Strangely enough Allan Burns (1809), who lived about the same time, considered disease of the myocardium to be less frequent than that of the valves. Later on, in 1834, the great Irish physician William Stokes insisted that the symptoms associated with evidence of valvular disease depended on the state of the myocardium and not on the valvular lesions themselves; in particular, he studied the softening of the myocardium in typhus fever, correlating it with physical signs. "It is," he said, "in the vital and anatomical condition of the muscular fibres that we find the key to cardiac pathology, for no matter what the affection may be, its symptoms mainly depend on the strength or the weakness, the irritability or the paralysis, the anatomic health or disease of the cardiac muscle." As he could hardly recognize diffuse myocarditis, which is now usually detected by microscopic methods, he conducted his studies mainly on fatty degeneration, of which he described two forms: (1) cases corresponding to what we now know as chronic arterio-sclerosis or chronic interstitial nephritis, but, excellent as were his clinical descriptions of these groups, the pathological basis of fatty degeneration which he attributed to them was erroneous; (2) heart-block, now known as "Stokes-Adams disease." Unlike Corvisart, Stokes realized that important changes may exist in the heart without corresponding physical signs. Fatty degeneration had indeed been first noticed by Corvisart and described by Laennec; in this country Richard Quain was the first to recognize it.

PATHOLOGY OF MYOCARDIAL DISEASE.

Modern cardiology has done much to bring order out of the chaos of cardiac arrhythmias, but now what we are most wanting knowledge about in any given case is the condition of the myocardium. Granted that it may not be difficult to decide in the case of a particular patient that there is some affection of the myocardium, though this is by no means always easy to make out, what we specially require to know is how much of the myocardium is affected and what part of it.

It so happens that in most of the organs of the body—for example, the liver, lung, or kidney—the exact amount or part of the organ which is devitalized and put out of action is not of much material importance; but in the case of the heart we want to know not merely that the myocardium is diseased, but what part of it is affected. Thus if the disease is confined to the auricles, the prognostic outlook is much more favourable than if we have reason to believe that the ventricles are also affected. Again, if the ventricles are affected, it is of greater importance if the lesion is situated near the apex or at the interventricular septum than if it is situated in other parts of the ventricular wall.

Now the muscle of the heart may be affected pathologically in two different ways: (*a*) by fatty changes; (*b*) by fibroid changes; and these are often combined together in varying proportions.

Fatty Infiltration.

When the changes take this form, the fat infiltrates the heart muscle, spreading along the main fibrous septa and even between individual muscle fibres, but there is no substitution of fatty material for muscular substance as occurs in fatty degeneration; it is rather a degeneration from the overlying layer of fat around the heart. It is more common in males and rare before middle age. It is invariably accompanied by a certain amount of fatty degeneration, but the converse is not always true. It is always greater on the right side of the heart and is usually associated with general obesity. In fatty infiltration more or less dilatation of the cardiac chambers is usually present,

* The St Cyres Lecture, delivered at the National Hospital for Diseases of the Heart, June 6th, 1929.

often accompanied by hypertrophy. The symptoms specially to be noted in fatty infiltration are cyanosis with dyspnœa on exertion, together with giddiness or faintness; there may also be some œdema about the ankles and along the tibiae at night.

Fatty Degeneration.

Here the heart substance is paler and softer than normal, and the heart muscle has a faded leaf colour. The musculi papillares will usually have a streaky appearance—the so-called "tabby-cat" striation—due to the interspersion of pale strands of fattily degenerated muscular substance among healthy fibres. Without the microscope it can hardly be recognized satisfactorily. Muscle lying closely beneath the endocardium tends to be more affected than that which is nearest to the pericardium. When advanced the fatty degeneration leads to a disintegration of the muscle fibres of the heart and their consequent replacement by fibrous tissue. Most commonly it is situated in the left ventricle and is rare in the auricles. In the left ventricle it is the papillary muscles, the adjacent muscle on the posterior walls, and the septum which most often show fatty degeneration. In cases of anaemia and aortic disease it is the left ventricle which is most affected, while in chronic pulmonary disease and in mitral disease it is mainly the right ventricle. Fatty infiltration and fatty degeneration differ in their site rather than in their essential nature. Fatty degeneration is most common in severe anaemias, chronic alcoholism, chronic renal disease, severe cases of typhoid fever, and in fatal phosphorus and arsenical poisoning. The primary change in these cases is atrophy of the muscle substance, invasion of the fibres by fatty matter being secondary.

There are no characteristic symptoms of fatty degeneration, with the possible exception of angina pectoris, which is often associated with fatty degeneration of the heart, though by no means always; more common symptoms, perhaps, are syncopal and apoplectic attacks due to defective pressure in the arterial system. Nor can it be said that there are any physical signs which are characteristic of fatty degeneration; it is rare to find much œdema, and probably it never occurs in a case of uncomplicated fatty degeneration. Until the disease is far advanced the diagnosis of fatty degeneration of the heart is far from easy; yet it is a condition which is frequently associated with sudden death, it may be during exertion or excitement or after a full meal. Rupture of the heart is one mode of termination, and may take place on very slight provocation. In the obese, cardiac failure is due to the relative smallness and weakness of the heart muscle—that is, the incapacity to meet the demands made upon it by the condition of general corpulence. In some fat but muscular individuals the heart is correspondingly large and muscular, while symptoms of cardiac insufficiency do not appear; as a rule, however, the heart becomes incapable of that driving power necessary to force the blood through the extensive system of capillaries which have been created for the supply of new adipose tissue. Sometimes fatty degeneration may signify simply an excess of physiological activity. In old hearts with coronary sclerosis even the bundle of His may be thoroughly fatty, and yet there may be no apparent diminution of conductivity; even well-marked fatty deposits may appear without giving rise to any clinical evidence of heart failure.

Fibroid Heart.

We now turn to the more important form of destructive disease of the heart muscle—namely, myofibrosis, or fibroid disease of the myocardium. Probably all individuals who after middle age have shown some cardiac symptoms have hearts in which fibroid changes in the myocardium would be found after careful microscopic examination. Like fatty degeneration, fibrosis of the heart muscle is the lesion most commonly associated with sudden death. Of course, the vast majority of patients with an impaired myocardium do not die during the early stages of the affection, so we do not have the opportunity of recognizing the nature of the changes which at the outset cause the impairment. By the time death has supervened the original changes have become greatly modified, either by becoming more pronounced or by the introduction of secondary alterations.

Pathologically, in fibrosis of the myocardium we find the connective tissue increased in amount and gradually replacing the muscle tissue. As a rule it is not distributed uniformly, but is scattered in little islets or bands throughout the myocardium. These fibroid patches are generally situated deeply, and do not always extend to the surface; they may be of any size or shape, and are most commonly found in the left ventricle, the parts specially affected being in the following order: (1) musculi papillares; (2) the apical third of the left ventricle; (3) the lower part of the septum ventriculorum; (4) the posterior wall of the left ventricle about the junction of the upper and middle third. Fibrosis rarely begins in the right ventricle, but may invade it by extension from the left. Foci of fibroid degeneration, when not very extensive, may not seriously interfere with the functional integrity of the heart, but in some instances they lead to a localized dilatation.

In the hearts of children fibrous tissue is scanty; not till about the age of 30 is connective tissue apparent, and it reaches no considerable development until the decade 40-50. This gradual increase of connective tissue may be a strengthening rather than a weakening of the chamber of the heart; it may, in fact, be a regenerative or auxiliary fibrosis in which a substantial part of the fibrous tissue is laid down in support of the muscular tissue. More usually, however, there is a substitutive fibrosis in which the genuine muscular fibres are supplanted by fibrous tissue. In the same heart both kinds of fibrosis, the substitutive and what might be called the protective, are sometimes mingled in varying degrees. It may be noted that connective tissue is a less resistant tissue and its elastic limit narrower, so that when once it is outstretched it cannot recover, but it is tougher. When the circulation is slowly interfered with by sclerosis of the coronary arteries, atrophy of the muscle fibres takes place without destruction of the connective tissue, and the shrunken and atrophied fibres are gradually replaced by fibrous tissue. It is the condition of the coronary circulation which, of necessity, dominates the nutrition of the heart.

Coronary Obstruction.

The most usual pathological cause of fibrosis is obstruction of the coronary arteries, which impairs the nutrition of the heart muscle. The sudden and complete closure of a main branch may lead to instant death; short of this it produces an infarct, though the lesion may be smaller than the area which is anatomically supplied. It is still possible for the cardiac muscle to be nourished through the foramina Thebesii, which are present in all the chambers of the heart, though they are more numerous on the right side; generally they are thought to be venous in function, and proceed from the muscular substance of the heart. Even though gross infarcts of the myocardium may occur, healing may still ultimately take place. If the obstruction of the coronary arteries is gradual the onset of symptoms is necessarily insidious and the course of the disease is essentially chronic. In consequence of the alteration and slow obliteration of the coronary vessels two forms of sclerosis of the myocardium appear: (1) *Hard sclerosis*, which is characterized essentially by fibroid tissue poor in cellular elements, containing at most a few leucocytes in the lymphatic spaces. (2) *Soft sclerosis*, which is distinguished from the former by its great vascularity. This sclerotic condition is the consequence of the alteration and slow obliteration of the vessels—that is, an arteritis obliterans in the fine arteries of the myocardium followed by ischaemia of the corresponding areas.

Coronary occlusion, however, need not always imply myocardial decay; even considerable hypertrophy of the heart may coexist with coronaries obliterated by atheroma. The myocardium, too, may remain quite normal even in a condition in which the coronary arteries are calcified. We must assume in such cases that the vessels of Thebesius have been able to carry enough blood from the interior of the ventricles into the myocardium to prevent any very serious loss of its nutrition. On the other hand, there may be a very severe and extreme change of the whole heart muscle, chiefly of the left ventricle, in which the part is

converted into a dense, hard, fibrous structure, diffuse, knotty, and nodular, without any noticeable dilatation or disease of the coronary arteries. The coronary arteries are so often affected because of (1) their high origin in the aorta, where blood pressure is at its maximum, (2) their structure, which is mainly muscular, (3) their numerous and acute curves and their continued activity in supplying blood to tissues constantly in action, and (4) their relationship to the constantly contracting heart, which exposes them to jerks and contusions.

OTHER CAUSES OF MYOCARDIAL DISEASE.

Though coronary sclerosis is an important cause of myocardial degeneration it is by no means the only one. Thus, valvular lesions may bring about degenerative changes of the myocardium by perverting cardiac metabolism and giving increased work to the heart. The disturbance of the nutrition of the heart results from lack of healthy blood on the one hand and defective removal of waste products on the other. Thus, aortic stenosis lessens the amount of blood sent into the coronary arteries, while mitral stenosis, through the stasis which it induces in the right heart, interferes with an adequate flow from the coronary veins. Regurgitant lesions on the left side of the heart also cause myocardial degeneration; they exert their effect upon the heart walls largely through the increased strain upon them. In heart strain there is a disproportion between the demands made upon the heart and its supply of nutrition. When hypertrophy exists the heart requires more nutrition than normal, and if dilatation at the same time prevents it from getting this supply then there is sure to be myocardial degeneration.

Apart from these more intrinsic causes of myocardial disease there are also various extrinsic ones. These include (*a*) excessive physical toil and hardship; (*b*) luxus consumption, combined with too little exercise and too much alcohol and tobacco; (*c*) raised blood pressure from the production of toxins within the alimentary canal and their absorption into the circulating medium; these toxins may also exert a directly injurious effect upon the myocardium; (*d*) exhausting diseases—for example, cancer, chronic dysentery, chronic suppurating diseases, and pernicious anaemia; (*e*) chronic infection arising in connexion with such diseases as cholecystitis and appendicitis; (*f*) poisoning by phosphorus and arsenic; (*g*) most of the diseases which give rise to acute myocarditis; and (*h*) syphilis.

Syphilis, quite apart from its effect on the coronary arteries, is a most important cause of myocardial disease. It may affect the heart either by forming gummata, which vary in size and number, and which may break down and give rise to aneurysm of the heart or undergo cicatrization; or by causing the replacement of cardiac muscular tissue by a round-celled fibroid tissue which, whether it occurs as nodules only or as a more widespread change, interferes with the heart's contraction, though it cannot be said to give rise to any distinctive symptoms. After death it is not possible to tell whether the changes in the myocardium are or are not syphilitic, except in those cases where there are actual gummata.

Myocardial disease is rarely if ever universal, and the local distribution of the fibroid or fatty changes is dependent upon local and, most commonly, on vascular causes. It so happens, however, that the visceral vessels may be most seriously affected without any evidence of change in the arteries, which are accessible to examination. It is our ignorance of the condition of the coronary arteries in any given case which makes it almost impossible to estimate this, the most important factor, at its true value.

DIAGNOSIS.

The recognition of myocardial disease is by no means easy, but amid much diversity of detail there is always the same background—namely, cardiac incompetence; it is, in fact, doubtful whether there can be any cardiac incompetence without some myocardial disease. From the clinical standpoint there are two main groups of myocardial disease.

1. *Latent Myocardial Disease.*

In this group the symptoms referable to the heart are latent, or so disguised as to escape recognition, and the existence of heart disease is not realized till sudden death has occurred. To these latent cases belong the sudden and unexpected deaths which not infrequently occur among middle-aged or elderly and apparently robust men. They are sometimes reported as apoplexy, but they are really instances of cardiac paralysis or sudden heart failure. This latency is due to the insidiousness of the changes going on in the heart muscle and to the position in which these changes occur—for the seat of the disease may lie in the septum, which has been called the "vital centre." It is in these cases that a bulging of the heart wall may occur, producing what is known as "aneurysm of the heart." Examination by a competent physician would probably reveal signs of general cardiac hypertrophy, together with some raised tension of the pulse. The myocardium may, for a time, respond to the heavy demands made upon it by an ever-increasing thickness of its walls; not, however, by a true hypertrophy of its muscular elements, but by a false hypertrophy due to the growth of connective tissue.

2. *Cases with Cardiac Insufficiency.*

In this group the symptoms of cardiac inadequacy are more or less conspicuous—namely: limitation of the field of cardiac response as shown by breathlessness on moderate exertion; palpitation; dizziness, which may be slight and transient or may amount to an annoying vertigo; epigastric fullness or pain, which the patient attributes to indigestion; and slight oedema about the ankles.

General myocardial weakness may be diagnosed when, in middle life, sometimes later on, manifestations occur of a chronic, gradually increasing cardiac weakness, a feeble pulse, sometimes very rapid, sometimes very slow, a tendency to syncope, and an extreme feeling of general weakness with increasing languor and apathy. The question naturally arises, Can myocardial degeneration be suspected before any symptoms have shown themselves?

In arriving at an answer the following points may be helpful.

1. The presence of distinctly sclerotic arteries, not only the radials but other accessible vessels.
2. The existence of an abnormally high blood pressure.
3. Increased area of deep cardiac dullness, especially towards the left, with often a triangular outline.
4. An aortic second sound, which is accentuated, and has a peculiar ringing and metallic quality.
5. At the apex a first sound, which may be high pitched and valvular, and apparently less intense than the second sound in the same area.
6. A distinct, usually harsh, systolic murmur in the aortic area, and occasionally after exercise a soft systolic murmur accompanying the first sound at the apex.
7. Urine increased at night, and giving evidence of nephritic changes.
8. An abnormal pulse rate; but the varying rate depends on so many factors that it is not easy to recognize which factor is the cause in any given case.
9. Abnormal rhythms, as in auricular fibrillation, auricular flutter, and pulsus alternans. Not infrequently extra-systoles are due to some damage to the conducting mechanism of the heart.
10. Lastly, an electro-cardiogram may be helpful. As a rule, electro-cardiographic tracings are mainly useful in cases of arrhythmia; when the rhythm is normal, apart from showing the preponderance of the right or left ventricle, they do not give much definite information. An inverted T wave in the first or second lead is a clear indication of myocardial degeneration; unfortunately, however, a normal T wave in these leads does not give any guarantee that the myocardium is sound. Some observers attach significance to the size of the ordinary T wave; in my opinion not much reliance can be placed on this sign in the diagnosis of the condition of the myocardium.

Diagnosis of the Severity of the Lesion.

Chronic myocardial disease is hardly ever observed alone; it is nearly always associated with different manifestations of arterio-sclerosis, and above all with renal sclerosis. A complexity of symptoms thus arises, in the midst of which it is difficult to distinguish which actually belong to chronic myocardial disease; indeed, this condition in the greater number of cases may be regarded as one of the manifestations of a general arterio-sclerosis.

So far no definite means have been discovered for estimating the strength or the weakness of the myocardium. The tests for measuring the contractile force of the heart are mostly fallacious. Physiology and pathology have shown

that the acceleration of the pulse rate after effort has no relation to the contractile force of the heart or the quality of the cardiac affection. True, indeed, some useful information may be derived by making observations on the pulse, respiration, and blood pressure just before and just after exercise, noting the time each takes to return to normal; these methods, however, give only a very general idea of the efficiency of the heart muscle. At present we have no definite mechanical device for testing the strength of the myocardium.

With regard to the functional capacity of the heart muscle, it is the degree of exhaustion of contractility which determines the nature of the subjective phenomena —for example, breathlessness, anginal symptoms, and cardiac asthma. When, however, the tonicity of the heart muscle becomes exhausted some dilatation of the heart ensues and we have the symptoms which result from this dilatation—namely, dropsy, oedema of the lungs, and so forth. When conductivity is damaged we then have either some degree of heart-block or auricular fibrillation; it is the position and character of the invasion of the myocardium which determine whether it will end in heart-block or auricular fibrillation. Even then when there is no doubt about the existence of myocardial degeneration it is still extremely difficult to make a certain prognosis.

PROGNOSIS.

The duration of life may vary from a few months to many years. In spite of the immense amount of work which has been done upon the heart we do not seem to have come much nearer to a knowledge of the strength of the cardiac muscle in any given case. The seriousness of the condition does not depend upon the total amount of muscle tissue which is converted into fibrous tissue, but rather upon the part of the heart which is affected.

In any given case could we be reasonably sure that the disease was confined to the auricles we could give a much more favourable prognosis. Probably this is why the condition of auricular fibrillation has such a varying outlook; it is essentially a lesion of the auricles, but, unfortunately, we have no means of being certain that the lesion is confined to them and has not extended to the ventricles, and it is this uncertainty which makes it necessary to give such a doubtful prognosis. I have had under my care for fourteen years a woman aged 61 with auricular fibrillation, and she does not seem very much worse now than when she first came under my care; I think one may feel fairly sure in this case that the ventricles have been but little affected. Often the history of the affection is a more useful guide to the prognosis than are the conditions present at the moment. The younger the patient the better as a rule is the prognosis, as there is less likelihood of serious degenerative changes having set in; after middle age such changes are usually present and compensatory hypertrophy is seldom re-established after it has once badly given way. The collection of numerous clinical details, both signs and symptoms, is comparatively useless in affording a prognosis unless we can form some adequate picture of the cardiac muscle at its work. For instance, is the income and output of the heart just balanced or is there a substantial reserve? If there is a reserve, is it disappearing, and how fast is it disappearing? We are too much in the habit of taking one lesion of the heart—it may be aortic regurgitation, or mitral stenosis, or auricular fibrillation—and basing on it our diagnosis, instead of considering each of these separate structural lesions as a part of the cardiac apparatus which is out of action, and estimating how much of the remainder is intact and healthy and able to carry on the necessary requirements of the circulation.

Heredity and the family history often give a valuable guide to the prognosis of myocardial disease. There are some families whose members seem to have a myocardium which begins to fail soon after middle age, without any definite antecedent disease. The outlook will usually be better when the myocardial impairment appears to be due to some rheumatic antecedent, because in these cases the lesion is more likely to remain stationary; when it is due to arterio-sclerosis the prognosis is definitely worse, because here the lesion is likely to be progressive. Intermediate between these two causes is syphilis; here, too, the lesion is apt to be progressive and to infect a large part of the myocardium. On the other hand, if the diagnosis is made early and active antisyphilitic treatment begun, the prognosis may be much better than that of the arterio-sclerotic cases.

Dilatation of the heart has been considered as evidence of myocardial impairment; it is not so necessarily, for dilatation is merely evidence of the exhaustion of the tonicity of the heart muscle, and is no exact measure of the quality of the myocardium. We have no measure of cardiac insufficiency; the pulse is generally accelerated in conditions of myocardial disease, but this is not an absolute guide. On the other hand, great slowing of the pulse, indicative of Stokes-Adams disease and pulsus alternans, is definite evidence of myocardial degeneration and of grave prognostic significance; so also are syncopal attacks. The presence of angina pectoris is of bad prognosis, since in the majority of cases there is more or less interference with the coronary circulation, and thus the possibility of sudden death. Also, when the myocardial degeneration is associated with chronic nephritis the outlook is very bad; above all, the development in these cases of a cantering rhythm, implying that the ventricular wall is subjected to a strain to which it must inevitably yield, indicates that death is not far off. On the other hand, a myocardium, though greatly weakened, may continue to perform its functions fairly well, provided no extra burden is put upon it. Any illness, especially acute infections, such as influenza, may prove to be the last straw.

When the changes in the heart muscle are fatty rather than fibroid the prognosis is very serious; the more corpulent the individual the worse is the outlook, since it is hardly likely that the obesity can be materially reduced without damaging the nutrition of the heart muscle. What makes prognosis so difficult is that the heart may be performing its work with but slight evidence of anything wrong, while all the time a process of degeneration is going on which is slowly undermining its resistance.

Finally, we might quote the saying of Huchard with regard to cases of myocardial disease: "Their evolution is latent, their beginning insidious, their course paroxysmal, their progress interrupted, their visceral complications various, and their explosions of cardiac insufficiency are sudden."

TREATMENT.

The first thing to consider is the state of the heart as a whole rather than the individual lesion which has presented itself. These patients require guidance rather than definite treatment. At the outset not only physical, but mental exertion must be reduced. We have to ask ourselves how much of the heart muscle is intact; whether there are causes at work which are likely to have a constantly weakening effect upon the myocardium; or whether the lesion is practically confined to the mitral or aortic valves or auricles and likely to be stationary. The problem before us is how to prevent any further impairment of the cardiac reserve and how to make the best of the sound heart muscle which is left. Obviously we cannot in the least modify the condition of the muscle fibres of the heart when their disease is far advanced, nor can we do much to arrest the progress of the deterioration when it has reached a stage at which it is recognizable through symptoms or physical signs. In the treatment of myocardial degeneration we have to consider climate, diet, and exercise.

Climate.

It is most important to find a climate which is mild and equable, sheltered from winds and rain, and having as much sunshine as possible; on the whole, the sea coast, except of the Mediterranean, is best avoided. The patients should not go to high altitudes, especially if they have high blood pressure. The effect of a rarefied atmosphere is to increase the rate and diminish the volume of the pulse, and to increase the depth and frequency of the respirations. But very few patients have a free choice in the matter of climate, so we have to make the best of their immediate neighbourhood. We should, then, look out for a gravel or sandy soil at a moderate elevation, where the rainfall is

below and the sunshine above the average and the water not hard, conditions best realized in England in Kent, Surrey, and Sussex. The house should face towards the south, and there should be protection from the north and east; obviously it should not be situated on the top of a hill, and the immediately surrounding country should not be too hilly.

Diet.

If the patient has exercised moderation in eating and drinking there is *no reason to alter* his habits because some myocardial weakness has been discovered. But most patients have not been moderate, and for them there should be definite dietetic restrictions. In patients past middle age, with some degree of arterio-sclerosis and a somewhat high blood pressure, we should naturally reduce the intake of meat and enjoin abstention from meat soups and rich gravies; with advancing years a more or less vegetarian diet is better for most people, though we have to beware of flatulence and the trouble incident thereto, such as abdominal distension and palpitation. It is important that the food should be eaten slowly and thoroughly masticated. Drinking large quantities of fluid increases the labour of the heart, and should be stopped; fluids should be taken at the end of meals. Tea and coffee are permissible, but in cases of raised blood pressure their use must be sparing; they tend to excite the myocardium, and whatever puts unnecessary work upon it helps to produce its ultimate enfeeblement.

It is well to disabuse the patient's mind of the idea that alcohol will increase or sustain his strength, but if he has been in the habit of taking it in moderation there is no reason why he should not be allowed to continue to do so. In so far as it helps him to digest his food it is beneficial, but it is better taken in the form of light wine than as beer or spirits. With some people the habit of smoking has become so deeply rooted that life without it seems almost unbearable; here again we should certainly not be too rigid, for anything which promotes the attainment of mental and moral calm is most important. It is important always to inquire into the strength of the tobacco; strong tobaccos, as in Havana cigars, must be banned, for they often accelerate the heart, and sometimes seem to augment the blood pressure. It is, however, essential not to fuss the patient unduly by a too meticulous restriction of diet; it was wisely said by Montaigne, "C'est ennuyeux de conserver la vie par un régime trop sévère."

Exercise.

It is well known that the strength of the skeletal muscles is increased by exercise; no doubt the heart muscle is not strictly analogous, for the mere fact of its continued beat involves some exercise; still, if the whole body is quiescent it is hardly possible to maintain the tone of the cardiac muscle, and a certain amount of exercise, provided it is kept within strict limits and there is no dyspnoea or oedema, is therefore essential for myocardial health.

Gentle walking exercise is beneficial in the early stages of myocardial incompetence, but patients must begin their walk at a slow pace and increase their speed only as they find exercise and breathing grow easier. In particular, they should be warned against walking when there is a strong or cold wind, and forbidden to carry heavy parcels. The plan of moderate hill-climbing, as originated by Oertel, is often helpful in cases where the myocardium retains a fair measure of integrity. The principle underlying this line of treatment consists in the ascent of gentle inclines at a speed that does not cause dyspnoea or palpitation. Only when such activity can be surmounted with ease is a steeper grade to be allowed. Golf in very strict moderation may be allowed.

Whatever outdoor exercise is permitted certain restrictions should be imposed. (1) Patients must not take exercise immediately after eating; in most cases they should remain quiet for at least an hour. (2) Walking, or indeed any other exercise, should not be indulged in to the point of fatigue. (3) In cases showing some indications of incompetence rest in the recumbent posture must be insisted on at the close of exercise. Some cases are certainly helped by "resistant exercises" and Nauheim baths, or by breathing exercises and light gymnastics. These medical gymnastics are specially helpful for patients who are obese or have abdominal fat in excess, and whose heart muscle is consequently flabby and lacking in tone; but it is essential that the myocardium should be fairly sound. Such exercises are intended to ease the work of the heart; whenever they cause palpitation or actual dyspnoea we know that the strength of the myocardium is being taxed, and not lightened of its labours. They should be performed with the assistance of some person who is trained to this work and will know how to avoid carrying the various movements to the point of causing embarrassment to the respiration and circulation. These exercises may be practised even when the patient is confined to bed, but they should stop short of producing any cardiac distress as manifested by increased frequency of the pulse. Almost any form of muscular exercise may be beneficial which promotes easier breathing and a more active circulation without producing great fatigue. Clothing should be warm, but tight clothing is specially to be avoided by women with high tension, since whatever occasions pressure upon the abdomen tends to raise blood pressure by acting on the splanchnics.

When the stage of incompetence is reached there are no measures for the treatment of myocardial insufficiency different from those applicable to the broken compensation of valvular disease.

HYDATID DISEASE AS A CLINICAL PROBLEM:

SOME NEW ZEALAND EXPERIENCES.

BY

D. W. CARMALT-JONES, M.D., F.R.C.P.,

PROFESSOR OF SYSTEMATIC MEDICINE, UNIVERSITY OF OTAGO, N.Z.

As is well known, *Taenia echinococcus*, the cestode parasite responsible for hydatid disease, completes its life cycle in two stages, which are passed in animals of separate species. As a rule the taenia stage is passed in the dog (definitive host), and the cystic or hydatid stage is very frequently passed in the sheep (intermediate host), but since the cystic stage may also occur in man, and since shepherds require dogs for the management of their flocks, "hydatid disease" in man is of fairly frequent occurrence in pastoral countries such as New Zealand, the personnel of the sheep stations becoming infested through their dogs.

Nevertheless, even in pastoral countries hydatid disease frequently presents a clinical problem of great difficulty. In a review of 90 cases in Dunedin Hospital it was found that an incorrect diagnosis had been made in 45.[1] Fairley, in a paper advocating the complement fixation test, reported in 1922 that of the cases admitted to Melbourne Hospital in ten years only 40.7 per cent. were diagnosed correctly before operation.[2] The likelihood of the disease is constantly impressed upon students; in any routine lecture upon haemoptysis, for instance, the common causes will be given as "phthisis, mitral stenosis, chronic bronchitis, and—in this country—hydatid of the lung"; and whereas in England the injunction is given: "In cases showing symptoms or physical signs of obscure origin—think of syphilis," in New Zealand the injunction is rather "Think of hydatid." Nevertheless, people frequently fail to think of it. This paper gives some account of the reasons for the obscurity of the condition, and also of some of the forms in which hydatid disease has been found to occur.

One reason for the difficulty in diagnosis is that the disease, formidable as it is, is not really very common. Sir Louis Barnett, a very close student of the subject, estimated twenty years ago that the incidence in New Zealand was about 100 new cases a year; he now estimates it as approaching 150, which is at much the same rate, allowing for the increase in population.[3] The number, therefore, that comes under the observation of any single medical man is not great; the 90 cases in Dunedin Hospital, of about 300 beds, represent the admissions for

twelve years—only 7 or 8 per annum, distributed among a staff of some eight physicians and surgeons. The number admitted to the large Melbourne Hospital, with 430 beds, was 182 in ten years.

It is very important that the disease should be recognized when it is present, and that any accessible cyst should be operated upon and removed as soon as possible, for reasons which the following figures will indicate. The total mortality for all cases treated in New Zealand is about 16 per cent., and the mortality is far higher among cases in which there is suppuration in the cyst, an accident to which all cysts are liable. In the 90 cases at Dunedin Hospital 19 suppurating cases were operated upon, with 52.7 per cent. deaths; 7 cases were not operated upon, and all died—doubtless they were too ill for operation; 63 non-suppurating cases were operated upon, with 6.3 per cent. of deaths; one case is not accounted for. It is desirable, therefore, to anticipate the onset of suppuration by removal of the cyst. Quite apart from the importance to life of early operation, the diagnosis of hydatid cyst is one which no surgeon is anxious to make to his surprise on the operating table. The reason for this is that any leakage of hydatid fluid into the tissues is likely to be followed by metastatic infection; consequently no operation is undertaken when the condition is suspected without careful preparation to avoid this accident, and materials are always provided for appropriate treatment, which may be impracticable if the cyst is found unexpectedly.

As noted above, only some 40 to 50 per cent. of the cases quoted were diagnosed correctly before operation, but it should be stated that these figures are taken from records completed some years ago, and they refer to diagnosis by symptoms and physical signs only; they have largely stimulated research into laboratory methods of investigation. Of late years the Casoni skin test, the complement fixation test, and improved skiagraphy have greatly facilitated diagnosis in cases where hydatid disease is suspected, and the routine employment of the complement fixation test in hospitals has much to recommend it in any sheep-raising country. It is stated that with the aid of laboratory tests correct diagnosis has been raised from 40 to 80 per cent. These tests are briefly referred to in later paragraphs.

A consideration of the biology of the disease explains the lack of specific symptoms and the variety of physical signs which are liable to occur in it.

The life-history of *Taenia echinococcus* is well known, and need only be briefly described. The adult worm is a parasite of the dog, and the cystic stage is passed as a rule in herbivora, chiefly sheep and cattle, and occasionally in man. The development in man is thought to be identical with that in the sheep and other intermediate hosts. Actually, cattle are rather more commonly infested than sheep, but the disease is probably spread by sheep, because dogs are frequently fed with sheep's offal, but rarely with cattle offal. Roughly speaking, in a country where hydatid disease exists among sheep all sheep-dogs stand the risk of becoming infested and are consequently dangerous to man. On the other hand, with regard to town dogs, some extended observations carried out by Otago University students in a public health study supported the view commonly held that town dogs, provided they do not frequent slaughter-houses, do not become infested with *Taenia echinococcus*.[4]

As will be shown immediately, the chief sites of infestation in sheep and man are in the liver and the lungs, both parts of the sheep with which dogs are commonly fed, and which they eat with avidity. It is probable that if the liver and lights of all carcasses were destroyed, and never given to dogs, hydatid disease would be abolished, but a small practical acquaintance with the conduct of a sheep station is enough to show that any advice of this kind is at present a counsel of perfection.

The dogs appear to suffer no disability as a result of ordinary infestation, though in laboratory animals, overfed with hydatid material, enteritis, ulceration, and death may occur. Sheep farmers do not recognize any symptoms among their animals from the worms, although there is some reaction on the part of the dogs' tissues, and their blood serum gives a positive result to complement fixation tests with hydatid antigen. From dogs experimentally fed with hydatid material there is some difficulty in recovering viable ova, but the complement fixation test with their blood serum soon becomes positive. The absence of symptoms in infected dogs is of interest, since humans with non-suppurating hydatid cysts suffer from no symptoms other than those due to pressure, with the exception of occasional skin lesions.

To return to the life-history of *Taenia echinococcus*. The adult worm infests the small intestine of the dog; it is very small, about 5 mm. in length, and it lies parallel to the villi of the dog's gut, to which it is very similar in shape and size. It consists of four segments; the head has a double row of hooks and four suckers, and finds attachment between the villi near their bases. The terminal segment, which contains the ova and which ultimately ruptures, is visible when mature on the surface of an infected duodenum if removed from the dog's body and laid open, but immature worms, which are much more numerous, are only to be found by careful search; many are deeply embedded in the crypts of Lieberkühn, where they probably escape the action of vermifuge drugs.

The ova are passed in the dog's faeces, and in stock animals infestation occurs from contamination of pasture. Not very much is known of the period of viability of the ova or of the conditions of temperature and humidity which are most favourable to them. Dévé of Rouen, however, has shown that they resist prolonged desiccation and also soaking in water.

Sir Louis Barnett is of opinion that human beings almost always become infested as the result of handling dogs, ova being thus picked up from dogs' coats, and conveyed to human mouths, rather than through the contamination of plates from which dogs have fed. It is also likely that infestation most commonly occurs in childhood, for indeed working shepherds do not very often handle dogs. Infestation through contaminated vegetables is probably of rare occurrence. It may be of interest to note that there are about as many sheep in Great Britain as in New Zealand, but in the latter country the proportion of sheep to population is 18 to 1, the highest in the world, and there is one dog to every eleven persons. The low actual incidence of hydatid disease among the population is perhaps worthy of remark.

The ovum when passed by the dog consists of a hard striated capsule containing a "hexacanth embryo." Whether swallowed by man or herbivorous animal, it hatches out under favourable conditions in the stomach or duodenum, bursting open like a hen's egg. The embryo escapes and "claws a passage" through the mucous membrane into one of the radicles of the portal vein, by which it passes to the liver of the host. In most cases when infestation occurs the embryo is lodged in some part of the liver, where the great majority of hydatid cysts are found. If it passes the liver and reaches the right heart it is likely to be arrested in the lung, the next most frequent site. It is rare for embryos to pass through the lungs and reach the general circulation, but if they do they may be found anywhere, as will be seen when the human cases are considered. There is no particular site of election in cases infested through the general circulation.

The embryo, when it reaches the liver, or any other site, may be destroyed by the tisues, which form "antibodies" to it, as is indicated by the serum reactions of infested patients. If it survives and reaches maturity it develops into the fluid-containing cyst. This is formed of two layers, ectocyst and endocyst, and it is surrounded by a fibrous pericyst, the adventitia, formed by the tissues of the host. The endocyst, or germinal layer, produces numerous "brood capsules," which ultimately become small vesicles which float inside the cyst, attached to its wall by a fine pedicle. Within the brood capsule the scolices develop, and are finally attached each by a small pedicle to the inner surface of the brood capsule, and so float inside it. The scolex is a minute oval body just visible to the naked eye; it contains invaginated the row of hocklets and the suckers which form the head of the fully developed worm. If the cyst is ingested by a dog the scolices evaginate and become attached to the small intestine of that definitive host, and develop into the complete worms of four segments.

The hydatid cyst often contains "daughter cysts." Dew[6] suggests that if during the life of the intermediate host the endocyst or germinal layer of the cyst is injured or its vitality otherwise threatened, "daughter cysts" are formed within the mother cyst, inside which the development of brood capsules and scolices proceeds. The only limit to the size of a cyst appears to be the capacity of the host to contain it. Barnett has reported a "colossal hydatid cyst"[5] of the abdomen from which he evacuated and measured eleven gallons of hydatid material besides what overflowed into dressings and was lost. This quantity must have occupied about one and three-quarters cubic feet, and weighed about eight stone.

If a cyst is ruptured within the body accessory cysts are likely to develop wherever the fluid penetrates and carries living scolices; consequently if a hydatid of the liver is ruptured, metastasis throughout the peritoneal cavity is not infrequent; this is called "secondary echinococcosis." This may occur as a surgical disaster if a cyst is unexpectedly disclosed at operation. If the cyst happens to be dead it is sterile, and no metastasis occurs; that, however, is a fortunate accident.

"Hydatid disease" in man depends on the presence of one or more of these cysts in some part of the body, generally the liver, from which the peritoneum is often secondarily invaded. The next most frequent site is the lung, and either a primary cyst may occur there or the pleura or lung may be invaded through the diaphragm by a cyst in the liver. If the embryo passes the lung and reaches the left heart it may be arrested in any part of the body. In the 90 cases of the Dunedin series 103 sites of infestation were noted (doubtless some of the cases were readmissions with recurrences; these have not been separated). The various sites were as follows:

Liver	56	72
Peritoneum	16	
Lung	16	
Brain	4	
Kidney	4	
Subcutaneous tissues	3	
Mediastinum	2	
Spleen	1	
Bone	1	

Dévé of Rouen (quoted by Dew[6]) gives the following distribution among 2,727 cysts.

Liver	76.6
Lung	9.4
Muscles and cellular tissues	5.2
Kidney	2.3
Spleen	2.1
Bones	0.9
Orbit	0.2
Brain	0.6
Miscellaneous	2.2

The Dunedin cases are therefore fairly typical, and it will be understood that when a hydatid cyst occurs in some important organ, such as brain or kidney, the doctor in charge will not be likely to have seen many similar cases. Unusual sites are more often discovered in children than adults, since in them a relatively small cyst exercises greater pressure. As in the dog so in the man, although specific antibodies are developed, and can be demonstrated, there are no recognizable toxaemic symptoms, unless suppuration occurs, when they are due to the superimposed infection, and unless the cysts cause mechanical interference, there is nothing about a patient who harbours them by which their presence is to be suspected.

Clinically few signs are to be depended upon in the diagnosis of hydatid disease. Cysts of the liver generally produce deformities of the upper surface, and there may be surprisingly little downward displacement of the lower edge. There are no symptoms unless there is some disturbance of function in an organ from pressure or irritation, so that the patient comes complaining of symptoms suggesting cholecystitis, pleurisy, hydronephrosis, or peritonitis, and there is little to call hydatid disease to mind. "Hydatid thrill," when present, is unmistakable, but it is very rare. Barnett[7] has described it very carefully; he has only found it seven times in the examination of over 300 cases; in one of these he was good enough to demonstrate it to me. He distinguishes it from the fluid thrill occasionally obtained in any thin-walled cyst close to the abdominal parietes. He calls the true thrill an "exquisite spring-like vibration, which is quite distinctly prolonged beyond the moment of percussion, and which is associated with a remarkable drum-like resonance heard on auscultatory percussion." He has found it only under the following conditions. "(1) The mother cyst has been close under the parietes. (2) Its walls have shown signs of degeneration leading to a slackening of the high normal tension that exists within the usual hydatid cyst. (3) Some large daughter cysts have been present, not closely packed, but having room to vibrate in contact with the wall of the parent cyst."

As mentioned above, laboratory tests have been introduced and improved of late years, but they are by no means infallible; those generally used are the white blood count, for excess of eosinophil leucocytes, the complement fixation test, the Casoni skin test, skiagraphy, and the macroscopic or microscopic detection of hydatid material evacuated from the body by any means and out of any site.

Eosinophilia may be present, but is by no means constant. Barnett's "colossal" case only showed 4 per cent. of eosinophil leucocytes, and Hercus[8] states from the department of bacteriology of Otago University that only about 35 per cent. of cases show an eosinophilia of more than 5 per cent. Eosinophilia when present is suggestive, and has led to the correction of other diagnoses in many instances, but it only occurs in one case in three; eosinophilia in sputum has before this led to the diagnosis of hydatid of the lung.[4]

The complement fixation test was first applied to hydatid disease by Ghedini in Italy in 1907, and has since been extensively used in many parts of the world. In Australia its application was worked out by N. H. Fairley,[2] and in New Zealand, independently, by Hercus.[8] Like most tests of the kind it is conclusive when positive, but a negative result does not exclude the possibility of hydatid disease. It is an immune reaction, and depends on the stimulation of the tissues by the presence of hydatid material. But, as has been mentioned, the tissues of the host form a fibrous capsule round the cyst which may effectually prevent the escape of its contents into the tissues, in which case the complement fixation test is likely to be negative. It has also been mentioned that daughter cysts occur if the endocyst is injured, which promotes leakage; consequently in cases of cysts containing daughter cysts this test is generally positive, whereas in unilocular cysts it is often negative. It happens that cysts of the liver often contain daughter cysts, whereas cysts of the lung are often single. In cases of dead cysts the reaction is negative.

The Casoni skin test is done in the same way as the skin tests for sensitization to pollens and foodstuffs and the like, but it produces both a "superficial" and a "deep" reaction, of which the latter, the more important, is delayed for some hours. The Casoni test is more persistent than the complement fixation test, because, once sensitized, the tissues retain their power to react to the direct stimulus of the antigen for very long periods, whereas if the cyst dies the serum soon ceases to contain antibodies demonstrable by the complement fixation test. The skin test, of course, is made in search of an "anaphylactic reaction"; it may be negative in unilocular unleaking cysts, and the reaction may be abolished if the tissues are flooded with excess of hydatid material, as in the case of rupture of a cyst. It will be understood that, with a patient's tissues sensitized, the rupture of a cyst, or even its exploratory puncture, may induce anaphylactic shock of any degree of severity, and death has undoubtedly been caused by it. Symptoms occur in the systems usually affected by anaphylaxis: cutaneous, gastro-intestinal, respiratory, cardio-vascular, and nervous (Dew). In the majority of cases of leakage, however, they are not very severe, and may easily be missed. As Freeman[9] has stated of toxic idiopathies in general, the reactions vary "from a shock producing coma to a scarcely perceptible malaise."

Skiagraphy.—My colleague Dr. C. C. Anderson has recently discussed the radiological diagnosis of hydatid infection,[10] with emphasis on the following points. Such diagnosis is easy in sites where there is sufficient contrast in permeability to *x* rays between the cyst and surrounding tissues, as in bone and lung. The typical shadow thrown

by a cyst is ovoid, but it is liable to distortion; it is normally a uniform shadow due only to the fluid, so that if the fluid becomes inspissated in a dead cyst the shadow cast is indefinite, but the adventitia around a dead cyst may be calcified, with a typical shadow. Suppuration may greatly obscure the picture. In the liver the chief indication of a cyst is irregularity in the upper border of the organ; in the lung the ovoid shadow is generally unmistakable; diagnosis of a cyst within the peritoneal cavity is difficult.

Clinical examination, blood counts, serum and skin reactions, and *x*-ray examinations are all seen to be fallible, but the diagnosis of the disease can be rendered absolutely certain by the demonstration of hydatid material derived from the patient, when this can be obtained. One hooklet or one fragment of laminated ectocyst is pathognomonic, and their discovery in material evacuated by a patient is of the same diagnostic value as is the demonstration of tubercle bacilli in the sputum from a case of suspected phthisis.

Hydatid cysts may be passed from most of the orifices of the body; not infrequently a "thing like a grape skin" is coughed up from the lung. Hydatid material, possibly bile-stained, is sometimes passed per rectum, and cysts have been passed per urethram and from the uterus. Scolices or hooklets may be recovered from sputum, urine, discharge from sinuses, or from fluid obtained by exploratory puncture. The fluid obtained by puncture of a healthy cyst, without suppuration, is water-clear, like cerebrospinal fluid. If it contains broken-down material it resembles dirty water, not serous fluid. Sometimes a quantity of clear saltish fluid is coughed up if a cyst ruptures in the lung. It is very undesirable to puncture a hydatid cyst, and it should never be done if the condition is suspected and a diagnosis can be arrived at by any other means. The risks are those of anaphylactic shock and secondary echinococcosis.

The following cases of hydatid disease are among those seen by myself, either in consultation or in hospital practice, during some nine years in New Zealand, the total number of which is, *ex hypothesi*, not large, and they indicate what difficult problems may be presented by the condition.

CASE I.—*Hydatid of Liver: Symptoms of Pleurisy.*

A woman, aged 34, three weeks before admission suffered from pain of sudden onset, described as passing across the stomach; it was diagnosed and treated as being of alimentary origin, without benefit. It lasted several days and then suddenly ceased, but was followed by severe pain in the right chest, and difficulty in coughing and breathing, fever, and rapid pulse and respirations. She was then admitted to hospital. The diagnosis of pneumonia was made, with fluid at the right base, but very little was obtained on puncture; later on, a needle was passed through the chest wall and diaphragm and watery fluid containing hooklets was obtained. The cyst was opened and about two quarts of fluid and daughter cysts evacuated. There was a very long convalescence, and the patient was deeply jaundiced for a long time.

In this case hydatid was suspected, because the patient had been operated on twenty years before for a cyst of the liver. The hydatid complement fixation was positive, but there was no eosinophilia. Without the assistance of the history there would have been little here to suggest the presence of a hydatid; the skiagram only showed a "large indefinite shadow" in the right thorax. This was a cyst of the liver, without demonstrable increase in its size, which produced pleural and pulmonary symptoms. Complement fixation was positive, blood count negative, skiagraph negative; Casoni test omitted on account of degree of illness.

CASE II.—*Hydatid of Liver: Jaundice and Signs Suggesting Cirrhosis.*

A boy, aged 13, was sent to me by Dr. H. F. Bernau, C.B.E., Napier, N.Z., with the provisional diagnosis of Hanot's cirrhosis of the liver, and raising the question of splenectomy. The boy had been deeply jaundiced for nearly a year, which had not much affected his health; that, however, was at no time very good. Recently he had complained of severe abdominal pain, localized vaguely as "across the abdomen"; there was an enormous smooth liver and a large spleen; the condition conformed to that of Hanot's cirrhosis as described in the textbooks, a very rare condition in this country. The blood count showed nothing remarkable, eosinophils 4 per cent.; the serum gave a direct van den Bergh reaction, but gave negative hydatid and Wassermann complement fixation reactions. It was decided to drain the gall-bladder. At operation the liver was found very big and hard and the gall-bladder was distended; the spleen was not so large as had been expected. The diagnosis appeared to be confirmed, when on the under surface of the liver a hydatid cyst was found, the size of a large apple. The operation was well borne, but in a few days there was profuse bleeding from the wound, from every possible mucous surface, and even from the nails, and the patient died despite numerous transfusions.

Neither the hydatid serum reaction nor the blood count was of any value in this case, the Casoni test was not then in vogue, and a skiagram would have shown nothing; the condition found at operation was a complete surprise to all persons concerned.

CASE III.—*Hydatid of Liver: Respiratory Symptoms.*

A man, aged 40, sent to me by Dr. D. G. Radcliffe of Balclutha, N.Z., was taken ill six weeks earlier with acute pain in the right side of the chest. At the time of onset no physical signs of disease were present in the chest; later on, however, signs suggesting pleurisy with a small effusion at the right base were found, but the patient declined both paracentesis and *x*-ray examination. The same condition was present for several weeks; the temperature was generally raised, sometimes reaching 102° F., with cough and pain in the side; there was loss of more than a stone in weight, and it was stated that there had been slight haemoptysis. Possible alternative diagnoses were phthisis, pleurisy, mediastinal tumour, or central pneumonia. On my examination there were marked wasting, bad colour, and a continual ineffectual cough. The heart was rapid, the chest thin, and the scalene muscles at work; there was an impaired note throughout the right lung, and feeble air entry, all very vague. A skiagram showed a large calcified hydatid cyst in the upper part of the liver; being calcified, it was dead. It was opened and drained by Mr. Gordon Bell, and was not found to be suppurating.

An unsuspected case, the diagnosis was made accidentally by the *x* rays; further laboratory observations were not required.

CASE IV.—*Hydatid of Liver: Pruritus.*

A married woman, aged 69, was sent to me on account of intractable and widespread pruritus of six months' duration, with gradual onset. It was worse at night and prevented sleep. There was no rash, and the condition seemed to be of the character of ordinary senile pruritus. On routine examination the patient was found to be much wasted, with a greatly distended abdomen and an enlarged and irregular liver. I sent the patient back to her doctor with some suggestions for symptomatic treatment of the pruritus, and raising the question of a neoplasm of the liver. This recalled the fact that two daughters had suffered from hydatid disease; the abdomen was explored, and a hydatid cyst evacuated from the liver, after which the pruritus ceased.

Here the family history, which is included in ordinary clinical examination, suggested the diagnosis; laboratory examinations were not made.

CASE V.—*Hydatid of the Lung: Symptoms of Pleurisy.*

A woman, aged 20, was admitted to Dunedin Hospital under my colleague Dr. Frank Fitchett; she said that she had a sense of "splashing" in the chest; there was a history of pleurisy six months previously. There were signs of fluid in the right chest up to the third rib anteriorly, but the posterior aspect was resonant, and air entered throughout. It was suggested that there was pleural effusion in front, but that the posterior part of the pleural cavity was obliterated by adhesions from the previous inflammation. A skiagram showed an oval shadow in the right chest reaching as high as the fourth rib, the upper border of which was very sharply defined, the lower border merging with the opacity of the liver. A needle was inserted and 30 ounces of colourless fluid, like water, were removed; after this a new skiagram showed a cyst wall, presumably the pericyst, with an inner wall partly separated from it, above the horizontal line of the remaining fluid. A large unilocular cyst of the lung was found at operation. The Casoni test, before operation, was negative.

As mentioned above, cysts of the lung are often unilocular, and, as such, unlikely to leak and induce immune or anaphylactic reactions. There was no eosinophilia. The laboratory tests were thus misleading, otherwise the chest would not have been aspirated; no harm resulted. The *x*-ray and blood tests were at variance; the diagnosis was clinched by the demonstration of hydatid material.

CASE VI.—*Hydatid of Brain.*

A youth, aged 16, was admitted to Dunedin Hospital under Mr. J. Renfrew White for consideration of orthopaedic treatment for hemiplegia. The patient had become completely blind and hemiplegic, apparently from intracranial tumour, at the age of 6 years. His skull had been opened by Barnett in hopes of saving his sight, and a hydatid cyst the size of an orange had been found and evacuated, but too late for any improvement in vision.

The diagnosis was unsuspected and made on the operating table. There is no record of tests.

CASE VII.—*Hydatid of Lung: Symptoms of Phthisis.*

A man, aged 34, was operated on for hydatid of the lung with haemoptysis in 1910. He joined the army in the war and went on active service. In 1916 he suffered from haemoptysis, and was invalided, under suspicion of tuberculosis. He suffers from recurrent bronchitis, and is frequently an in-patient of Dunedin Hospital, but tubercle bacilli have never been found in his sputum. He gives an intense Casoni reaction.

A case clinically resembling phthisis, but hydatid had been previously demonstrated, and the skin test was positive.

CASE VIII.—*Tuberculosis of Lung.*

A man, aged 32, was sent into Dunedin Hospital with haemoptysis and the provisional diagnosis of phthisis. Some consolidation was found at the base of the left lung, and the skiagram showed a "rounded shadow suggesting hydatid cyst." Dr. Hercus had then just completed his technique for the hydatid complement fixation test, which was negative in this case; there was no eosinophilia, and he insisted that no hydatid was present; the chest was explored and only thickened pleura and scar tissue were found, but negative results to the laboratory tests do not now carry as much conviction.

The converse of Case v; the *x*-ray suggestion was incorrect, the laboratory findings gave accurate information. It is thus seen that the diagnosis between hydatid of the lung and pulmonary tuberculosis may be a matter of difficulty; both are among the causes of haemoptysis. Also, hydatid of the peritoneum may be confused with tuberculous peritonitis. Barnett's colossal hydatid was diagnosed as the latter, and a child of 10 in the hospital with the diagnosis of tuberculous peritonitis was found to have an eosinophilia of 38 per cent., and proved to be suffering from hydatid disease.

I am not aware of any recorded association between hydatid disease and haemorrhage, except from the lung, but I have had experience as follows: Case ii died of haemorrhage after operation; it is true that he was deeply jaundiced, and that such cases are notoriously grave operative risks on account of bleeding; Case i, a case of hydatid of the liver, jaundiced after operation, showed no special inclination to bleed; the case may, however, be grouped with the following.

Three cases have been recently admitted to the women's medical ward with severe gastric haemorrhage; all had previously been operated on for hydatid disease. Dr. Radcliffe has informed me of a case of metrorrhagia in a young woman who was found to be suffering from hydatid of the liver; after its removal the uterine haemorrhage ceased. Certainly all cases of hydatid disease do not bleed severely, but several cases are quoted which have been found to do so; such bleeding may, possibly, be a manifestation of anaphylaxis. The fact is merely noted in this place.

Briefly to analyse these seven cases of hydatid disease. None of them had symptoms or physical signs which in themselves pointed at all strongly towards this disorder; it is extremely improbable that the diagnosis would have been even suspected except in a pastoral country. In two (Nos. i and vii) the patients' history gave the clue, hydatid material having been previously demonstrated; in one (No. iv) the family history was suggestive. These three admitted of diagnosis on ordinary clinical grounds, and in one of them this was supported by the complement fixation test and clinched by demonstrating hydatid material, and in another the Casoni test was positive. In two (Nos. ii and vi) the diagnosis was made on the operating table; in one of these the laboratory was misleading, and in the other (treated fifteen years ago) there is no record of investigation. In two (Nos. iii and v) the skiagrams gave correct information, though in No. v the complement fixation and skin tests were misleading and hydatid material had to be withdrawn to clinch the diagnosis. Excluding Case vi, which occurred before the era of specific tests, five of these cases were diagnosed before any major operation was undertaken; only one in five operations was actually discovered on the table. This is an approach to modern claims in accuracy of diagnosis.

It is evident that the diagnosis of a very serious disease, to which the inhabitants of a sheep-raising country are peculiarly liable, may present great difficulties, but that if the risk is constantly kept in mind, a study of family and personal history, physical examination, skiagraphy, blood and skin reactions, and pathological investigations will generally discover the presence of hydatid, though any single investigation may be misleading. The treatment is evidently surgical, and it is important that cysts, if present, should be removed.

I have to thank both Sir Louis Barnett and my colleague Professor Hercus for kindly criticizing this paper. Several amendments and additions which it now contains were made at their suggestion. I have also to thank Dr. Roland Fulton for kindly allowing me to use his analysis of the Dunedin cases.

THE TREATMENT OF PERNICIOUS ANAEMIA BY LIVER.*

BY

CHARLES H. MELLAND, M.D.LOND., F.R.C.P.,

HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

THE liver treatment of pernicious anaemia was introduced by Minot and Murphy in America, and their first series of cases was published about three years ago. Dr. Spencer of Newcastle had some patients on this line of treatment early in 1927. One of the first, if not actually the first, in this neighbourhood was my patient W. H. P., at the beginning of July, 1927, and I had several others who started upon it about the same period. Since then I have had about forty cases under my care on this mode of treatment, and one can now draw some general conclusions as to its value, particularly its value as compared with methods of treatment previously employed.

It may be said in general that with the exception of four patients who were very ill when first seen, and who died within a few days, and the same number whom it has been impossible to trace or who failed to persevere with the treatment, all are alive and reasonably well to-day—the majority very well and following their regular work. One has died from intercurrent disease.

But at most the period of treatment has been little more than a year and a half, and a good deal less than this in many, and I find, on going through my records, almost as satisfactory results in a good many cases from our older methods of treatment. For a fair estimate of its value, therefore, it must be compared with some of the results in these older cases. Take the following cases, for example.

CASE I.

Miss G., a patient of Dr. Vipont Brown, was first seen in October, 1911; she had then been ill for about a year. Red corpuscles 2,340,000 per c.mm., haemoglobin 56 per cent., colour index 1.22. The appearance of the blood films was in every way typical. Under treatment she made a satisfactory recovery, but relapsed in the following summer, and was an in-patient under my care in the Ancoats Hospital from July, 1912, until early in 1913. In the early part of this period she proved intolerant to arsenic, but later took it well and made a good recovery. From this date she remained under the care of her own doctor. I saw her and examined her blood from time to time, but she remained free from relapse, and was able to follow her employment. About Christmas, 1925, she had an attack of influenza, and this brought on a typical relapse. She was readmitted to the Manchester Royal Infirmary early in 1926, and under treatment again made a rapid improvement. Her blood showed: on February 13th, 1926, red blood corpuscles 1,500,000 per c.mm., haemoglobin 33 per cent., colour index 1.1; on March 6th, red cells 2,100,000 per c.mm., haemoglobin 51 per cent., colour index 1.2; on March 28th, red cells 2,950,000 per c.mm., haemoglobin 62 per cent., colour index 1.05.

Unfortunately after her discharge I lost touch with her. She got into low water, she was now an elderly woman turned 60 years of age, and I learn that she died later on in that year. But she ran a course of sixteen years, during most of which time she was free from serious relapse and able to follow her employment.

* Read in opening a discussion at a meeting of the Manchester Medical Society, April 3rd, 1929.

CASE II.

A. C. was a patient in the Manchester Royal Infirmary as far back as 1899. Blood examination on June 11th, 1899, showed: red blood cells 1,210,000, haemoglobin 30 per cent., colour index 1.2; and on July 15th, 1899, red cells 3,560,000, haemoglobin 70 per cent., colour index 0.98. In all respects, both clinically and haematologically, he was a typical case. This improvement was maintained, and in November, 1901, more than two years after I had first seen him, I had him under my care at the Ancoats Hospital. A blood count in November, 1901, showed: red cells 4,180,000, haemoglobin 80 per cent.

I saw him at intervals till the summer of 1906, a period of seven years in all, or eight years from the beginning of his illness. He then had developed phthisis, and died from this without any return of his pernicious anaemia.

CASE III.

As rather a contrast to these two cases, here is the record of Miss M. She was first an in-patient at the Manchester Royal Infirmary in 1913, and had then been ill for about a year. Unlike the previous cases, she had no long period free from relapse; she had frequent relapses, and was readmitted to hospital, mostly under my care, eleven times between May, 1914, and September, 1924. On each of these occasions she made a satisfactory recovery, but only during one period—from August, 1917, to July, 1919—was she able to remain out of hospital for nearly two years. Out-patient treatment was carried out during the intervals. Finally, in 1924, associated with the relapse there were pronounced mental symptoms, which necessitated her being transferred to a Poor Law hospital, where she died.

CASE IV.

J. B., a patient of Dr. Bisset of Heywood. There was some suspicion when I first saw him that this patient had carcinoma of the stomach, but the examination of a blood film, on October 31st, 1917, was diagnostic of pernicious anaemia. He improved under treatment, but was a very difficult patient, and when he felt better he ceased attendance on his doctor. Consequently after his initial improvement he relapsed and in April, 1918, a blood count showed 2,220,000 red cells per c.mm. With the resumption of active treatment he made a rapid improvement, and by July, 1918, his red cells had risen to 4,600,000 per c.mm. Once more he neglected treatment, and by November, 1918, the red blood cells had again fallen to 1,970,000. From this date his response to treatment was less satisfactory; he made a partial recovery, which was followed by a speedy relapse, and in May, 1919, he dragged himself with difficulty to my consulting rooms and I concluded that that was the last time I should see him. His red blood cells were then down to 1,570,000 per c.mm. However, this was by no means the end. He took things to heart and stuck close to his treatment, and in October, 1919, when I fully expected to hear that he was dead, he appeared in bounding health with red cells 4,050,000 per c.mm. From this date he never looked back; he presented himself for examination in July, 1920, and his corpuscles were then up to 4,820,000. He had no further relapse; he remained perfectly well, although following out little if any treatment, and died from pneumonia in 1925, eight years after the disease first manifested itself.

It must be confessed, of course, that not all the cases under my care in these earlier days made such satisfactory recoveries or ran this long course. The reason in many cases, however, is not far to seek. Treatment on these older lines, which included full doses of arsenic, a variety of intestinal antiseptics, intramuscular salvarsan, and vaccine, requires great care. The dosage must be carefully adapted to the patient's condition. The dose of arsenic which is required during the active stages of the disease closely approximates to the toxic dose. During stages of recovery active treatment must be judiciously diminished or intermitted; the patient must be under constant supervision and, if practicable, periodic blood examination should be made in readiness to return to more active treatment on the first sign of relapse.

As a result inquiries have shown that cases that have been under careful medical treatment in hospital with surprisingly complete temporary recovery may, on leaving hospital, very commonly relapse, and may speedily die unless readmitted promptly, because it was impossible to get this careful and difficult treatment continued satisfactorily after leaving hospital; and the same must be said of only too many cases seen in private on single occasions, when an initial recovery has been only too liable to be followed by relapse and a fatal ending. But fortunately I can recall many exceptions where I have found practitioners who have collaborated enthusiastically, or where I have had the opportunity of seeing the patient from time to time and giving continued advice as to treatment. All the following cases are of interest from this point of view, and more especially so that they all show the transition from "pre-liver" to "post-liver" *period of treatment.*

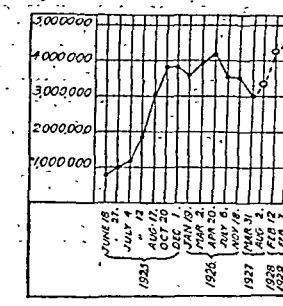
CASE V.

Mrs. C. (the late Dr. Derham Reid of Bolton and his successor, Dr. Brown). Blood examination showed:

	Red Cells per c.mm.	Haemoglobin per cent.
June 18, 1925	735,000	22
,, 27, ,,	915,000	—
July 4, ,,	1,275,000	38
,, 12, ,,	1,905,000	48
Aug. 17, ,,	3,142,000	72
Oct. 20 ,,	3,740,000	92
Dec. 1, ,,	3,740,000	86
Jan. 19, 1926	3,610,000	90
Mar. 2, ,,	3,880,000	103
Apr. 30, ,,	4,210,000	94
July 6, ,,	3,620,000	86
Nov. 18, ,,	3,680,000	87
Mar. 31, 1927	2,990,000	75
Aug. 2, ,,	3,390,000	80
Liver added.		
Feb. 12, 1928	4,290,000	95
Feb. 7, 1929	4,500,000	93

The patient had been ill for over a year before coming under treatment in a rather desperate state, with red corpuscles down to 735,000 per c.mm. She continued under treatment without relapse, though with a slight setback in March, 1927. She is perfectly well now and shows no signs of the disease.

The diagram below shows more graphically the progress of this case over nearly four years. The broken lines represent the course after start of the liver treatment.



CASE VI.

Mrs. R., a patient of Dr. Church Mann of Radcliffe. She was seen first on March 6th, 1926, but she had been ill then, with several ups and downs, for about two years. Her course under treatment is shown by the following figures:

	Red Cells per c.mm.	Haemoglobin per cent.
Mar. 6, 1926	1,530,000	35
Apr. 19, ,,	3,000,000	82
June 25, ,,	3,740,000	94
Oct. 12, ,,	3,760,000	88
Jan. 6, 1927	3,650,000	90
Apr. 27, ,,	3,580,000	90
Sept. 28, ,,	3,430,000	90
Liver treatment commenced.		
Apr. 1, 1928	4,350,000	95

and she is still, up to date, keeping quite well.

CASE VII.

Mrs. M. (a patient of Dr. Berry of Pendlebury). She was first seen on September 2nd, 1926, as an out-patient at the Manchester Royal Infirmary, and was an in-patient from September 7th to November 6th of that year. Following is a record of her blood:

	Red Cells per c.mm.	Haemoglobin per cent.
Sept. 13, 1926	650,000	14
Oct. 7, ,,	2,340,000	45
Oct. 20, ,,	2,800,000	68

She improved very rapidly under treatment, from an extremely low figure, but after leaving hospital she gradually went back.

Dec. 27, 1926	3,900,000	75
Apr. 1, 1927	2,960,000	70
July 22, ,,	2,160,000	52

Active treatment was then resumed with the addition of liver, and she was again an in-patient from August 16th to September 17th, 1927.

Aug. 17, 1927	2,250,000	56
Sept. 17, ,,	3,530,000	76
Nov. 25, ,,	4,488,000	91

But now, with the addition of the liver, she did not relapse on leaving hospital. On July 13th, 1928, the red cells numbered 4,576,000 per c.mm., and the haemoglobin was 90 per cent. She continued well until a few weeks ago, when she was taken ill

with some subacute abdominal trouble—probably tuberculous peritonitis—and died, without, however, any sign of a return of her anaemic condition.

It is of interest to note that the improvement after the addition of liver was little, if any, more rapid than on her previous admission without it, but that the red corpuscles rose to a higher figure, and that no tendency to relapse remained so long as she continued the treatment.

CASE VIII.

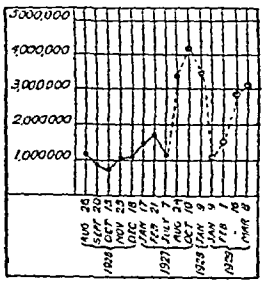
Mr. W. H. P. (a patient of Dr. Sidley of Eccles). I saw him first in August, 1926, but he had been recognized as suffering from pernicious anaemia since early in 1924, and had been ill for some little time before that date. The record of his blood shows:

	Red Cells per c.mm.	Haemoglobin per cent.	Colour Index.
Aug. 29, 1926	1,200,000	—	—
Sept. 23, ,, ...	948,000	20	1.05
Oct. 15, ,, ...	850,000	25	1.47
Nov. 25, ,, ...	1,090,000	32	1.6
Dec. 18, ,, ...	1,120,000	30	1.5
Jan. 17, 1927	1,410,000	35	1.5

It is noticeable how slow and imperfect was the response to treatment in this case, so that when he left hospital after four months' treatment, although he was a good deal better, the red corpuscles had not reached one and a half million per c.mm. As an out-patient on February 21st, 1927, the red blood cells numbered 1,624,000 per c.mm., haemoglobin 36 per cent.; on July 7th the red cells numbered 1,160,000. In the course of these months there had been a gradual falling back in spite of careful treatment. So he was readmitted and was restarted on active treatment, including now minced liver.

	Red Cells per c.mm.	Haemoglobin per cent.
Aug. 24, 1927	3,340,000	—
Oct. 10, ,, ...	4,264,000	—
Jan. 9, 1928	3,544,000	—
Jan. 9, 1929	1,764,000	20
Feb. 1, ,, ...	1,810,000	38
,, 16, ,, ...	2,730,000	58
Mar. 15, ,, ...	3,054,000	70

Here it is of interest to note that, in contrast to the slow improvement in 1926, the addition of the liver to his other lines of treatment brought about a much more rapid and complete amendment, and this was equally evident early this year when in consequence of some neglect of treatment he had a serious relapse at the end of 1928. This is all the more distinctly brought out by the following graph.



Here, then, we have this patient after some six years back at work and feeling quite well.

I will briefly refer to two other cases that have responded satisfactorily to treatment, part of the time without the addition of liver, part with.

CASE IX.

S. G. (Dr. Burrows Brown of Failsworth). Seen first on January 18th, 1924. A blood examination on that date showed: red blood cells 1,530,000 per c.mm., haemoglobin 38 per cent., colour index 1.24. Seen again in January, 1925; no count made, but doing well. January, 1928: Continued well, but recent partial relapse; red cells numbered 2,770,000 per c.mm.; liver added to treatment. In March, 1929, the patient was doing well; no sign whatever of anaemia; working, after a course of five to six years.

CASE X.

W. S. F. (Dr. Myers of Radcliffe). Seen first on November 26th, 1926. He had then been ill through the greater part of that year. His red corpuscles were down to 1,440,000 per c.mm. On March 30th, 1927, they numbered 4,220,000 per c.mm., haemoglobin 90 per cent.; on December 17th, 1927, 3,930,000 per c.mm., haemoglobin 86 per cent. From this date onward liver was added to the treatment, and he has continued perfectly well up to date.

It may be noted in these, as in other cases that have been published, that when under other methods of treatment the number of red corpuscles tends to stand at between 3,000,000 and 4,000,000 per c.mm., the addition of liver commonly brings the number to over 4,000,000. In some cases, however, this difference is not particularly striking; in others the rise with the addition of the liver may be still more remarkable. Thus, in one patient the red corpuscles rose from 2,770,000 to 6,000,000 between November 14th, 1927, and March 12th, 1928.

In every case I have given the liver in addition to the already described methods of treatment. This may be unscientific, but in such a grave disease I do not think we are justified in abandoning any line of treatment that has been well tried and has proved successful. When, however, recovery from the active phase of the disease has taken place it may be maintained, as a rule, with the liver alone, with little, if any, further aid from our other lines of treatment.

Summary.

From my study of these cases there are certain general conclusions at which I have arrived.

1. On our older lines of treatment, if efficiently carried out, *many, if not most*, cases of pernicious anaemia may be given many years of useful life; but there are practical difficulties in getting the treatment effectively applied, which consequently result in a large proportion of failures.

2. The introduction of the liver treatment has undoubtedly greatly increased our power of dealing with the disease; the improvement is more rapid and the advance in the number of red corpuscles is higher.

3. Continued treatment by liver will maintain the improvement, and it will do this more easily and with less meticulous attention to details than will our older methods alone. Consequently, though not necessarily more successful—as I have already demonstrated—it is undoubtedly more simple to carry out, and so there is much less risk of failure.

4. At the same time, whilst relieving the symptoms it does not appear to strike at the root of the disease, so as to produce a complete and lasting cure. So far as we can say at present, treatment must be continued, and, if given up, or insufficiently followed out, relapse will occur.

5. Though 6 or 8 ounces of minced liver ("potted liver") in the day is usually advocated, I have found in general that when combined with the older methods of treatment 4 ounces or even 3 ounces may be quite effective. This is of importance in the case of those who dislike the liver and take it only with reluctance.

6. When the red corpuscles have been raised to 4,000,000 or over a smaller amount of liver—3 or 4 ounces every other day, or even as little as 1/2 lb. in the week—will maintain the improvement, at any rate, if combined with some continued or occasional courses of treatment, in moderate degree, of the older methods of treatment.

7. It is important not to push the dose of liver too high or to keep on with the use of full doses too continuously. There is some reason to suppose that over-use may risk the production of gout or chronic nephritis. As in all other methods of treatment, its use must be guided by the consideration of the condition of the blood.

8. In those who have insuperable difficulty in taking the fresh liver, liver extracts, either solid or liquid, may be used. They appear to be equally effective with the fresh, but are very expensive.

9. Although it has been supposed that the liver treatment leaves the nervous symptoms untouched, I am not sure that this is the case. In three cases in which these symptoms were prominent and in which arsenic had appeared, whilst curing the anaemia, to aggravate the nervous symptoms, slow improvement has occurred with the use of liver and dilute hydrochloric acid. In many cases the slighter nervous symptoms, the numbness and tingling about the fingers and toes, have been materially improved.

10. Lastly, accurate diagnosis of the disease is of greater importance than ever it was.

PERNICIOUS ANAEMIA.

PRELIMINARY NOTE ON THE AFTER-RESULTS OF TREATMENT WITH LIVER.

BY

JOHN F. WILKINSON, M.B., M.Sc., PH.D., F.I.C.,

DIRECTOR OF THE LABORATORY FOR CLINICAL INVESTIGATIONS AND RESEARCH, MANCHESTER ROYAL INFIRMARY;

AND

WILLIAM BROCKBANK, M.A., M.D.CANTAB., M.R.C.P.,

HONORARY PHYSICIAN, THE MANCHESTER VICTORIA MEMORIAL JEWISH HOSPITAL.

(From the Laboratory for Clinical Investigations and Research, Manchester Royal Infirmary.)

WE have been investigating the after-results of all cases of pernicious anaemia admitted to the Manchester Royal Infirmary during and since 1925, and are publishing our preliminary observations in the hope that they will be of interest to other workers investigating this disease.

The cases fall naturally into two sections: (*a*) Those that received the usual treatment of arsenic and hydrochloric acid before the introduction of the Murphy-Minot diet. (*b*) Those that received the liver treatment, often in addition to the drugs mentioned. The total number of cases studied has been 80, of which 47 belong to the first group and 33 to the second. Briefly our observations are as follows.

1. Of the 33 patients who left the hospital on the liver diet about 50 per cent. are very well and 15 per cent. in good health except for the symptoms of subacute combined degeneration of the cord, at an average interval of twelve months from their discharge. Only two (6 per cent.) are dead; one did not take the diet after discharge, the other took it regularly until he died (aged 66) fifteen months later.

2. Of the 47 patients who were not prescribed the liver diet 50 per cent. are dead, at an average interval of ten months from discharge. The remainder, almost without exception, are now on the diet. Their progress is being watched.

3. The patients who have done best are those who have taken the liver raw or half-raw. Those who have eaten it well cooked have not done so well.

4. A history of tingling and numbness of the fingers and toes, presumably the earliest symptoms of involvement of the cord, was given by 44 per cent. of all our patients. Of those that are still alive and on liver treatment 52 per cent. have no such symptoms now; 11 per cent. are better, and the remainder (almost all of whom had alterations from the normal reflexes) are no better or are definitely worse. This suggests that liver treatment has no effect on the symptoms of subacute combined degeneration of the cord, once the reflexes show that there is organic disease in the central nervous system. The symptoms gradually become worse, although the patient's bodily health is much better.

5. Relapses do occur even when the patients are taking liver regularly, but they are not nearly so common (only six cases noted in our series) as they were before liver treatment was tried. Five of these cases were taking the liver well cooked, the sixth was taking it raw, but the relapse followed an attack of influenza.

6. Of the 47 cases of pernicious anaemia sent out without liver, only 2 had ever worked regularly before the advent of the liver diet; whilst of the 33 cases sent out on the diet 14 are back on full work and 5 are doing part-time work—a total of 57 per cent. at work.

7. During their periods as in-patients (an average of forty-five days in each case) the following alterations in the constituents of the blood were noted:

	Erythrocytes.	Leucocytes.	Haemoglobin.
Patients not on liver ...	+46%	− 8%	+49%
Patients on liver ...	+91%	+41%	+77%

Of the patients who have done well, almost all have retained some degree of anisocytosis and poikilocytosis; all have abundant platelets, and in all the staining of the erythrocytes is normal.

8. Diarrhoea and gastric disturbances appear to have been cured by the liver treatment, only one case of recurrent diarrhoea having been noted in a patient who is otherwise quite well. There are no indications that treatment by hydrochloric acid has any appreciable influence—most patients discontinuing its use after discharge. Inadequate liver diet, however, frequently causes a return of gastric discomfort.

9. Reinvestigation of the condition of the stomach by fractional test meals shows the following results:

(*a*) Achlorhydria persists in nearly every case. Only two exceptions have been noted, and these will be discussed in a later paper.

(*b*) The total acidities of all samples withdrawn are greatly diminished, being equivalent to 1.5 to 10.9 c.cm. (average 4 c.cm.) of N/10 alkali per 100 c.cm. gastric contents.

(*c*) Total and mineral chlorides, whilst showing parallel titres, give widely varying values in different cases.

(*d*) Peptic activity is very considerably diminished or negligible.

(*e*) The fasting contents in over 80 per cent. of the cases are less than 38 c.cm., the remainder falling between 50 and 80 c.cm.

(*f*) In practically all cases mucus is present in very marked amount in the fasting contents and frequently in the earlier samples of the test meals.

(*g*) Lactic acid is invariably absent.

(*h*) The stomach empties on an average in one to one and a quarter hours.

10. Several sequelae of the diet have been described in the literature. Our observations on them are as follows:

(*a*) Persisting eosinophilia (5 to 14.75 per cent.) occurs in patients taking the liver diet.

(*b*) Albuminuria has never been found.

(*c*) One case of venous (femoral) thrombosis has been observed.

We have to thank the physicians of the Manchester Royal Infirmary for permission to use their cases in the course of this investigation.

BRUCELLA ABORTUS INFECTION IN MAN.

REPORT OF A CASE.

BY

IVOR J. DAVIES, M.D., F.R.C.P.LOND.,

ASSISTANT PHYSICIAN, CARDIFF ROYAL INFIRMARY.

AND

W. CAMPBELL ANDERSON, M.D., B.Sc., D.P.H.,

CARDIFF.

IT has now been definitely proved that infection from the organism known as the *Brucella abortus* Bang, the cause of contagious abortion in cattle, may occur in human beings. Cases have occurred in America, Rhodesia, Italy, and Germany, with identification of the organism. It is probable that this infection in man is not rare, and if the possibility be borne in mind its incidence may perhaps be found to be not uncommon. In this country many likely cases have been recorded, but in which absolute proof through identification of the organism was absent.

Theodore Thompson[1] has recently published a report of a case of this infection in this country; he also presented a review of the literature concerning *B. abortus* infection in man and animals, and noted the similarity between *B. abortus* and *M. melitensis* and their associated diseases. Thompson[1] stated that this was the seventh authentic instance of the infection to occur in this country. Manson-Bahr,[2] Bamforth,[3] and Wordley[4] have also reported cases of undulant fever in which the blood agglutinated *B. abortus* or *M. melitensis* in high dilutions, but failed to demonstrate the actual organism. H. Harrison and G. S.

Wilson,[5] in an examination of 998 serums sent for Wassermann testing, and negative to this reaction, found when the serum was tested against *B. abortus* that 5.5 per cent. agglutinated this organism; the average titre was 1 in 64. The proportion of females to males proving positive was nearly two to one. A titre of 1 in 40 was not uncommonly met with, and is probably of no significance in the diagnosis of abortus fever. Forty-two serums sent in for Widal testing, and proving negative to members of the typhoid-paratyphoid group, have been examined for agglutinins to *B. abortus*; 26.2 per cent. agglutinated this organism to a titre of 1 in 10 or higher. The average titre was 1 in 336. The proportion of females to males proving positive was nearly two to one.

Harrison and Wilson[5] advanced the tentative conclusion that *B. abortus* is probably capable of infecting human beings in this country; and it is suggested that blood cultures and agglutinin tests should be made on all cases of undiagnosed pyrexia and of indefinite, occasionally febrile, maladies. A reference was made in their paper to an important contribution by M. Kristensen[6] of Copenhagen. He examined 1,177 Widal serums and found that 89 of them agglutinated *B. abortus* to 1 in 100 or higher. Blood cultures were made from 20 of these patients, and in 13 of them an organism indistinguishable from *B. abortus* was isolated. Of the 89 patients 68 were males and 21 females; no patient was under 13 years of age. Clinically the picture was that of undulant fever, with sometimes severe sweating, localized pains, bronchitis, diarrhœa, or enlarged spleen. Infection occurred apparently from contact with aborting cows or from drinking raw milk or cream.

R. A. Kern[7] of Philadelphia has made an admirable contribution on the clinical aspects of *abortus* infection, and concluded that it was widely prevalent in America. He stated that surveys have shown that up to 90 per cent. of herds are infected in some regions, and that practically no region is free. Infectious abortion has long been a serious economic problem in the dairy industry of America. To the question, In view of such extensive bovine infection, why so few human cases?—fewer than 40 are on record in his country—Kern replies that many cases have been overlooked because, owing to the variability of the disease, there is no characteristic clinical picture. He quotes Bassett-Smith[8] to the effect that Malta fever, because of its variety of forms, is seldom recognized in its early stages in the countries in which it is known to be endemic; most of the patients are treated for something else at first. Kern remarked that if this is true of Malta fever in its normal habitat, how much more likely will the bovine type of the disease be overlooked. He believes that there is as yet a very low index of clinical suspicion of the presence of the disease on the part of general practitioners, and as a result many cases are, in all likelihood, going undiagnosed. These comments are particularly valuable as only 7 cases have been reported in this country. Kern concludes that a clinical consciousness of the disease will lead to the routine testing for *Brucella* agglutinins in all undiagnosed fevers.

CASE REPORT.

Male, aged 44 years, director of music, robust, active, and fond of outdoor pursuits. He was of careful habits, except for a partiality to raw milk and cream. He had never lived abroad, and had not been out of this country for several years. On July 13th, 1923, he motored to Scotland from Wales, and spent a fortnight's holiday touring in the Highlands. Raw milk and cream were consumed at several places on the way, at farms in the country, and dairies in the cities, and also daily throughout his stay in Scotland. He was very tired at the end of the journey, but soon recovered, and enjoyed his holiday. On July 27th and 28th he felt much fatigued after a round of golf, and this was particularly noticeable as it came at the end of a good holiday. He was again tired after the return journey, and was not in his usual good health throughout September. During this month, and for some time before his holiday, he had been subject to eructations and flatulent discomfort. At home he usually consumed daily about a pint of a so-called certified milk, and occasionally small amounts of cream.

The acute stage of the illness commenced on October 2nd, through an abrupt onset resembling that of influenza, with general pains, headache, and fever, but without evidence of catarrh. The temperature was taken daily for a week, but not recorded, though it was raised throughout, and medical advice was not sought until later. Sweats of moderate severity followed the fever fairly regularly in the evenings, with an occasional feeling of chill just before the rise of temperature. He improved, and returned to his work for four days when his temperature was normal, but a feeling of malaise remained. A further fourteen days' holiday was spent at Bournemouth. The temperature was daily subnormal throughout this period, and some general improvement resulted. He returned home on October 7th, and was again fatigued; the temperature on the evening of this day rose to 100° F., and the acute stage of his illness lasting six weeks followed. The record of the fever was not commenced until November 4th, but during the previous week the temperature was regularly a little over 100° F. in the evenings and almost normal in the morning.

The Pyrexia.—The course of the temperature was that of an almost regular intermittent fever (see chart), most often 101°

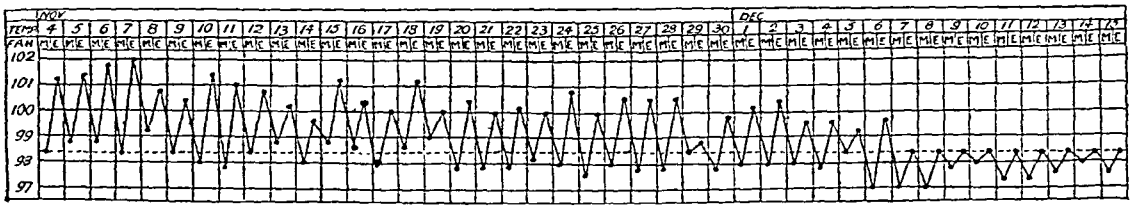


CHART TO SHOW THE COURSE OF FIVE WEEKS' INTERMITTENT FEVER.

for the first three weeks, and slightly lower afterwards. The reading was frequently normal or subnormal in the morning, rising as a rule at 5 p.m., and highest at 7.30 p.m., and often fell to 100° or 99° a few hours later. The highest temperature recorded was 102° at 5 p.m. on November 7th, but this reading was not repeated, and was probably influenced by the extraction of a few teeth. The fever was thus continuous over a period of six weeks without any afebrile intervals, except for one day towards the end of the fifth week of the acute stage. An afebrile period of over fourteen days' duration occurred soon after the onset, as has already been described. Profuse sweats, often drenching, which had a peculiar and disagreeable odour, occurred almost daily. Shivering attacks were not infrequent, and, more especially in the early stages, with a few rigors. Headache of some severity was complained of only at the beginning of the illness, being only slight afterwards. Pain was not a feature, and was absent except at the onset; slight joint pains were felt only in an early stage, before he was confined to bed. Constipation had been present for some time previously, and throughout the febrile stage, but was easily controlled.

Physical examination was almost negative. The tongue was thickly coated during the whole course of the fever. Much conservative work had been done in the mouth, and the gums appeared to be generally unhealthy. The abdomen was a little distended, but free from tenderness, and the liver and spleen were not palpable. No glands were felt. There was no rash. The heart and lungs were normal, except that the heart sounds lacked tone. The pulse rate on an average was 120 per minute during the course of the disease, and was very easily accelerated afterwards in the convalescence, and noticed by the patient. The blood pressure on November 6th was 130 mm. systolic and 80 mm. diastolic. Respiration was elevated with the rise of temperature, but was otherwise normal, and no bronchial catarrh was present at any time. The urine was normal, except for a transient slight glycosuria about the middle of the acute period. A diagnosis of oral sepsis was first made, and radical dental treatment was carried out on November 7th and in the week which followed. A streptococcal infection was considered likely as a susceptibility was assumed, owing to the occurrence in 1925 of an ulcer on the lateral surface of the tongue, which remained indolent for three months before healing took place. The Wassermann reaction at that time was negative.

The course of the temperature was unaffected by the dental treatment. The gums remained inflamed, spongy, with slight suppuration, until on December 1st a small, foul-smelling bit

of necrosed bone extruded, and healing of the mouth afterwards gradually followed. The temperature dropped to normal within a week of the separation of the necrosed bone, and no further attacks of fever have arisen up to the time of the report. The patient lost 14 lb. in weight in the course of the illness. Convalescence was slow, and five months later he had not fully regained his usual health, and had only recovered 2 lb. in weight. The tongue remained slightly furred, and he complained of precordial discomfort and aching in the region of the left shoulder. The heart's action was still impaired.

Clinical Pathology.—Examination of the blood on November 23rd showed no qualitative change in the red cells or malarial parasites. The blood count was as follows:

Red blood cells	4,500,000 per c.mm.
Haemoglobin	80 per cent.
Colour index	0.7
White blood cells	7,000 per c.mm.
Polymorphonuclears	50 per cent.
Lymphocytes	48 per cent.
Eosinophils	1 per cent.
Basophils	1 per cent.

Agglutination Tests.—On November 23rd the patient's serum was negative to the typhoid-paratyphoid group, but positive to the *Brucella abortus* in a dilution of 1 in 250. A week later the positive agglutination reaction to this organism had risen to 1 in 800, and this titre was maintained on each of the two following weeks. On March 20th, 1929, after three months' convalescence, the agglutination reaction to the *Brucella abortus* was completely positive in a dilution of 1 in 1,000. The tests were repeated on May 28th, when the agglutination reaction was found to be still positive, but the titre had now dropped to 1 in 200. The blood count was almost unchanged, except that the leucocytes had risen to 9,600 per c.mm., polymorphonuclears 50 per cent., lymphocytes 44 per cent. The leucopenia had thus disappeared, but the relative lymphocytosis remained.

Blood culture and urine culture were negative on December 13th, 1928. The Wassermann reaction was negative.

DIAGNOSIS.

The diagnostic problem, as Kern[7] remarks, is eminently one for the laboratory. The only solution lies in the routine use of the appropriate tests in all undiagnosed fevers. Hardy[9] has suggested that, until physicians generally are cognizant of the disease, all serums sent to State and municipal laboratories for Widal's test should be tested for the *Brucella* as well.

Blood culture and serum agglutination tests are essential. Urine culture may also be of value. The blood count in a case of *Brucella abortus* infection is that of a leucopenia with a relative lymphocytosis. There is no characteristic clinical picture. Fever is the only universal symptom, but there is no distinctive curve which may be continuous or undulatory with intervening afebrile periods. The continuous fevers may be sustained or remittent to an extent simulating that of septic infection or malaria. Some patients become progressively ill and soon seek advice; others are little disturbed by the infection, and may not take to bed at once, and then only for a brief period of the duration of the disease, or they may be wholly ambulatory. Kern[7] submits an important clinical observation: "One gets the impression rather generally that the patients are subjectively not so ill as their appearance and fever may seem to warrant." The patient whose case is now reported did not believe himself to be ill enough to warrant the services of a nurse.

DIFFERENTIAL DIAGNOSIS.

Brucella infection in symptomatology closely simulates that of other diseases, but, if borne in mind, suitable tests will usually be decisive. Septicaemia from hidden foci of infection must in particular be considered; also the typhoid-paratyphoid group, *B. coli* infection, tuberculosis, subacute bacterial endocarditis, leukaemias, pernicious anaemia, Hodgkin's disease, and malignant disease. A careful review of the previous health and habits, mode of onset, course of the disease, routine physical examination, and a close analysis of laboratory tests will rarely fail to lead to a definite diagnosis.

The case of Scott and Saphir[10] is of great interest because of the association with an infective endocarditis engrafted on an old mitral lesion. Blood culture yielded the *Brucella abortus*, and the serum agglutination reaction was positive in 1 to 1,000 dilution. At no time were streptococci found in the blood. The heart's blood yielded the *abortus* organism but no streptococci. The morbid anatomy was typical of infective endocarditis. No other source of infection was found. There was no actual proof that the *abortus* organism was responsible for the acute endocarditis, and the case was reported as "one of acute and chronic endocarditis associated with *Brucella melitensis* (*abortus*) bacteriaemia." It remains to be shown whether this organism will ultimately find a place in the bacteriology of infective endocarditis.

TREATMENT.

This is mostly symptomatic. Mercurochrome has been tried and appears to have been curative in a few cases. The drug is given intravenously in doses of 10 to 20 c.cm. of a 1 per cent. solution, and can be repeated once or twice if necessary after an interval of several days.

PROPHYLAXIS.

Infection of human beings by the *Brucella abortus* organism mainly arises through the drinking of raw milk. The remedy appears to be obvious, but probably incapable of universal adoption. The supply of milk is only second in importance to the water supply, and should be solely under the control of the municipal authorities, and not left to the caprices of private enterprise. Various methods of herd prophylaxis and treatment of infected animals have been proposed. Birch[11] recommends the detection and segregation of all infected cattle. Karsten[12] in Germany (quoted by Kern[7]) makes several valuable recommendations, and amongst others: (1) Blood agglutination tests in all animals in the herd, including the bull once a year. Reacting animals are to be killed or segregated. (2) In freshly infected herds in which less than 10 per cent. of the animals are involved, the disease is eradicable by killing the infected individuals, repeated disinfection of stables, and routine testing of the remaining cattle. He feels that these more radical measures are preferable to the therapeutic vaccination when the incidence of infection in a herd is low.

In Rhodesia infectious abortion in cattle has been made a notifiable disease. Infected herds are quarantined until six months after the last abortion or until satisfactory vaccination has been carried out; stables are disinfected, and reacting bulls are killed. Vaccine treatment of segregated infected animals seems to meet with fair success.

SUMMARY.

The case here reported is almost certain to be one of infection by the *Brucella abortus*; it is the eighth to be reported in this country, and the first from Wales. Actual isolation of the organism (for example, from the blood) would of course be necessary for absolute proof, but the clinical details are closely like those of published reports in cases where the organism was actually identified. The duration was at least nine weeks; it is impossible to be exact owing to the uncertain time of onset, as was also shown in a majority of the published cases.

The case was one of prolonged pyrexia of unknown origin until the blood was submitted to the agglutination test against the *Brucella abortus* organism, when the cause of the infection was discovered. The serological test was positive in high dilution. No local source for the infection could be traced.

We are much indebted to Dr. W. Parry Morgan, bacteriologist to the Cardiff and County Public Health Laboratory, for the pathological investigation.

SYMPHYSIS OF THE SPLEEN WITH THE LIVER: SPONTANEOUS RUPTURE OF THE RIGHT VENTRICLE AND SYPHILITIC AORTITIS.

BY

F. PARKES WEBER, M.D., F.R.C.P.

I ONCE examined a boy with considerable splenomegaly of uncertain nature in whom abdominal palpation suggested that the spleen might be closely adherent to the left lobe of the liver. In that case, which cannot be discussed here, one physician recommended splenectomy (there had been an attack of haematemesis and melaena), and indeed the possibility of real symphysis of the spleen with the liver was hardly entertained as possible. Such a condition of real symphysis, whether congenital or acquired, must be one of extreme rarity, and I never met with a certain example until recently at the post-mortem examination on a man, whose case was likewise noteworthy for other reasons.

The patient was a powerfully built man, aged 50, who for some years past had been ailing with oedema of the feet and dyspnoea on exertion. In the hospital the heart was much enlarged and there were typical signs of aortic reflux. The urine contained a trace of albumin and some hyaline and granular tube-casts. The brachial blood pressure (April 22nd, 1929) was 150 mm. Hg (systolic) and 40 mm. Hg (diastolic). There was some serous effusion in the right pleura. A blood count showed slight anaemia (3,760,000 erythrocytes and 11,100 white cells in the cubic millimetre of blood). He had never had rheumatic fever. On May 18th his temperature was 100.4° F., and there was evidently, as there had been of late, a feeling of thoracic pain or discomfort of some kind. About 8 a.m. he asked for drink, said he felt better after drinking, but became suddenly cyanosed and died in two minutes.

The necropsy (carried out by the house-physician, Dr. Scholtz, on the same day in my presence) showed right-sided serous pleural effusion and slight ascites. The pericardium contained about 100 c.cm. of blood and serum, and through a minute slit-like rupture, about one centimetre in length, in the anterior wall of the right ventricle (close to and parallel to the anterior interventricular groove, five centimetres from the apex), blood could be forced out in a fine jet on squeezing the heart. There was great hypertrophy of the left ventricle, and the enormous heart weighed 800 grams. The aortic cusps themselves were only slightly sclerosed, but the first part of the aorta was a little dilated and much thickened and sclerosed. Microscopically the aortic wall showed patchy small round-cell infiltration, chiefly of the middle and adventitial coats, certainly a result of syphilitic aortitis. Dr. J. G. Greenfield, who kindly looked at a section with me, pointed out that nearly all the infiltrating cells were characteristic plasma cells. The rupture had taken place between the columnae carneae at a spot where the muscle was only two millimetres in thickness. On microscopical examination of that region many of the muscular fibres were obviously atrophic.

The kidneys were rather large and together weighed 550 grams. Though the capsules stripped readily, the cortex of one of them had a slightly granular surface.

The spleen (about twice the size of the normal) was so adherent to the left lobe of the liver that at first sight it appeared to constitute an abnormal additional hepatic lobe. The area of the fibrous adhesion (symphysis) was larger than the palm of a large hand. The two organs together weighed 2,100 grams, and showed chronic congestion. Microscopical examination of the thin layer of fibrous tissue uniting the two organs showed little evidence of inflammation. Nevertheless, there were some perihepatitic and other chronic peritonitic adhesions present, and perhaps one cannot be absolutely certain that the symphysis of the spleen to the liver was congenital.

The specimens are now in the museum of the Royal College of Surgeons, London, and I am much indebted to Mr. T. W. P. Lawrence for assistance in examining them.

Mr. D. M. Greig, conservator of the museum of the Royal College of Surgeons at Edinburgh, has kindly drawn my attention to a report by De la Torre (*Presse médicale*, Paris, 1926, xxxiv, p. 669) on the case of a woman, aged 24 years, in whom a "tongue" of hepatic tissue about 70 mm. in breadth was connected with the uterus. The "tumour" was recognized by palpation, but operation was refused. A few months later she married, and, when eight months pregnant, the arch of hepatic tissue between the liver and uterus caused intestinal obstruction and the condition was discovered at operation. Mr. Greig observes that if an abnormally shaped liver can become adherent to the uterus there is no reason why a liver in the left hypochondrium should not become adherent to the spleen. Mr. Greig in this connexion mentions that Abernethy (*Philosophical Transactions*, London, 1793, lxxxiii, p. 59) reported the case of a female child, aged 10 months, in whom the liver extended equally into the right and left hypochondria. In that case, Mr. Greig adds, the extension of the liver to the left may perhaps have been etiologically connected with the fact that the child's spleen consisted of seven separate portions, to each of which a branch of the splenic artery passed.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HEADACHES OF PERIPHERAL ORIGIN.

OUR increasing knowledge of the numerous close connexions which exist between the periphery and centrally placed organs has helped us in recent years to understand the causes of this type of headache. It will suffice merely to mention the great clinical importance of Head's zones. I wish, however, to draw attention here to the connexion which exists between some infiltrations of the nape of the neck and headaches which may have persisted for years (sometimes dating from childhood) and from which the patient is rarely free for a day or a week at a time.

These infiltrations may sometimes be recognized by inspection, if the nape and other parts of the neck are carefully examined. (It is very important that the head should be held symmetrically for this purpose, as even a slight deviation may easily simulate pathological differences between the two sides.) By careful inspection very slight differences between the right and the left side may be observed, corresponding to differences in consistency which may be palpable. The three middle fingers are passed gently from above downwards, first on one side and then on the other, avoiding deep pressure to begin with. By this means it is possible to detect small differences in the consistency of the tissues on the two sides. In order to estimate with greater accuracy how deep these differences lie the pressure is gradually increased, care being taken to avoid too much force, as this would interfere with the sense of touch. Palpation is thus gradually extended to deeper parts.

When the whole neck has thus been palpated it is common to find here and there a smaller or larger infiltrated area of which the patient may be quite unaware, and which, curiously enough, does not always appear to be tender on pressure. These infiltrations are always diffuse; they are not circumscribed as "points" or "nodules"; they may be as large as the palm of a child's hand, and as regards depth may lie in the skin or subcutaneous tissue or extend through the muscles down to the bone.

The headaches, of which the patients may have complained for years, are not generally uniform in type. The patients suffer from attacks almost daily or at intervals of a few days; it is characteristic of this type of headache that it occurs in the morning on waking. The degree of pain also varies considerably: it is sometimes merely very unpleasant and at another time it may be very severe. It is noteworthy that only a proportion of the patients complain of a definite association of the headache with bad weather.

I consider the connexion between the above-mentioned infiltrations and rheumatism to be as follows. By careful examination it is generally possible to demonstrate a more or less intensive focal infection in the tonsils, teeth, pharynx, nose, or accessory sinuses. From these foci dead

avirulent bacteria or bacterial toxins pass into the blood stream and reach the various fascias, aponeuroses, and ligaments of the posterior part of the neck, which seem to have a remarkable special affinity for these toxins. Here they act as chemical stimuli, and thus induce inflammation with consequent infiltrations. I would emphasize that this condition frequently affects persons who are not primarily visiting the spa for treatment, but rather as *escort visitors who occasionally consult us for their* headaches. In other words, headaches in "apparently non-rheumatic persons" may originate in infiltrations in the nape of the neck; this condition occurs very frequently, and merits attention.

When the condition has once been carefully localized troublesome symptoms which have been present for years can be relieved in a short time (generally in two or three weeks), and complete absorption of the infiltrations can be effected. The treatment we adopt consists in local applications of mud in the form of packs at 40° to 45° C. (32° to 36° R., or 104° to 113° F.) for half an hour to an hour daily; in addition, we use careful massage of the infiltrated part and surrounding area, in which the help of some form of vibration apparatus which is not too strong may be useful. In our experience there are not many problems in medicine which can be solved so satisfactorily and with comparatively so little trouble.

L. SCHMIDT, M.D.,
Hon. Member of the Ligue International Contre le Rhumatisme, Bath of Pistany, Czechoslovakia.

Reports of Societies.

ROTATION OF THE FOETUS.

AT a meeting of the Edinburgh Obstetrical Society, held on June 12th, with the president, Dr. HAIG FERGUSON, in the chair, Dr. J. CHASSAR MOIR read a paper on the mechanics of internal rotation of the foetus.

Dr. Chassar Moir said that the subject of the rotation of the foetus had in the past brought forward so many varying and conflicting theories regarding its exact mechanism that it seemed desirable to open up the subject afresh. A theory to be valid must explain the movements of rotation which take place in normal and abnormal presentations. The rotation of the shoulders in a cephalic presentation, the rotation of the pelvis in a breach presentation, the rotation of the after-coming head, the rotation which occurred in the experiments of Dubois and of Edgar—all these facts had to be accounted for. The theory must also explain why on rare occasions the normal mechanism breaks down. The necessity for rotation was then illustrated by means of models, which allowed a "foetus" to escape when the occiput was anterior, but which became impacted on attempting to repeat the movement with the occiput in the posterior position. The structure of the birth canal was then considered, and reasons given for ignoring the slight differences in measurements of different cross-sections. The canal was a hollow passage of even contour and calibre, and was sharply bent at its lower end. The shape of the foetal head and trunk was discussed in detail, and a demonstration given by photographs, of direct tracings of the head, and also of tracings and photographs of frozen sections made by the speaker. From these investigations it was possible to draw the following conclusions: (1) Moulding profoundly alters the shape of the foetal head. (2) The flexed and moulded foetal head must be regarded as a bluntly pointed cylindrical structure very nearly symmetrical about its long axis. The apparent asymmetry of the face and mandible was due to the fact that the cylinder was obliquely cut off at its base. (3) In the flexed and moulded foetal head the occiput and sinciput ceased to be recognizable as projections. (4) At the level of the "girdle of contact" the foetal head was circular on cross-section and the presenting part beyond this was a symmetrically shaped dome. The apex of this dome, which impinged on the pelvic floor, was a point which coincided with the central axis of the head. (5) From frozen sections it was shown that the point about which bending occurs in the neck is very nearly equidistant from the front and back of the neck.

Dr. Chassar Moir, in a criticism of the theories of the mechanics of rotation, said it was obvious that the foetus must be studied in the shape and form which it assumes when rotation occurs. The head was an appendage of the trunk, and the two must be considered as a whole. Yet almost all theories were based on the study of a dried and *unmoulded head which had been severed from the trunk.* Sellheim's theory was discussed, and it was shown that some of the many criticisms with which it had been faced were invalid. There was contained in this theory an unassailable truth. The theories of Paramore and of Young were criticized. Dr. Young's model was described. The speaker believed that the rotation which it demonstrated played some part in parturition, but was not the essential cause of rotation of the foetus. Berry Hart's theory failed because the part which first touched the pelvic floor was the domed-shaped presenting part. This point was in the direct line of the long axis of the head. Lateral pressure on it could only cause tilting of the head. It could not cause rotation, because rotation required an eccentric pressure. Four facts were necessary to explain rotation: (1) The foetus was driven through a canal by a force acting from above. (2) This canal was sharply curved at its lower end. (3) The flexed and moulded foetal head was a cylinder which was attached to the trunk, which formed a second cylinder. (4) These cylinders could be bent on each other with unequal ease in different directions. By picturing the forces which arise when such a body is forced through such a canal, it could be seen that rotation must inevitably occur until the part of the body which was least easily bent coincided with the concavity of the lumen of the canal. The head, because of its flexed attitude, and because of the structure of the neck, could only with difficulty be further flexed. On the other hand, it could be readily extended. Lateral flexion required an intermediate *degree of force.* Figures obtained by actual measurement confirmed the statements. Descriptions and demonstrations were then given of a model designed to illustrate these mechanical facts. By altering the strength of various elastic bands the effects of the different forces could be studied. This model showed both short and long internal rotation of the occiput. Certain additional factors contributed to the rotation. The head when at rest was angled on the trunk. This aided rotation. A second model was demonstrated in which this angle was reproduced. This model also showed the apparent asymmetry due to the face and mandible of the child. The artificial vertebral column was more elaborate than in the first model. The point at which the vertebral column joined the head was accurately determined by the information gained from the frozen section of a foetus. This model demonstrated both short and long internal rotation with even greater ease than the first model. A mathematical explanation of the forces causing the rotation was then given. This theory was shown to apply equally readily to the rotation which occurred in a face presentation. Here, again, the head was a cylinder, and this time it could be bent most easily in the direction of flexion and least easily in the direction of extension. Forward rotation of the chin therefore took place. The theory also explained the rotation of the after-coming head. Rotation of the shoulders in a cephalic presentation, and of the pelvis in a breech presentation, could be accounted for by the unequal flexibility of the trunk in two directions. Short rotation could therefore occur. Long rotation required three unequal *flexibilities.* The occasional persistent occipito-posterior, and persistent mento-posterior cases were accounted for by the lack of complete flexion in the one case, and of complete extension in the other. The head could then be almost as easily flexed as extended. The essential factor was therefore missing, and rotation consequently failed.

In conclusion, Dr. Chassar Moir said that the cause of rotation could be broadly stated thus. Part of the driving force exerted on the foetus in causing it to pass through a curved canal was absorbed by that body, and converted into certain unequal lateral forces. These pressures, reacting from the walls of the canal, brought into play tangential forces which caused rotation of the foetus.

Reviews.

BLOOD GROUPS.

Few fields of biological research have experienced so great a rush for claims as "isoagglutination." Apart from the work of early prospectors, Landois (1875), and Shattock, Landsteiner, and others at the beginning of this century, the subject was entirely untouched. To-day Professor L. LATTES presents his *L'individualité du sang*,[1] a third edition of his well-known book, with a bibliography, which he hints is really incomplete, extending to 54 pages. The first edition of this work was written in Italian and published in 1923, the second appeared in 1925 and was in German; the present volume, written in French, reproduces the excellence of the previous editions, and the author seems to have brought it as well up to date as the rapid growth of an immature subject will permit.

The unfortunate confusion created by the numbering of the Jansky and Moss groups, which are given in several tables in parallel columns, is largely removed by adopting the V. Dungern Hirszfeld formula—O$a\beta$, Aβ, Ba, ABo (capital letters signifying agglutinogens, Greek letters agglutinins, O and o being absence of agglutinogens and agglutinins respectively)—which is independent of group numbers and at the same time gives a graphic representation of the group constituents. The author deals at length with the inheritance of blood groups on Mendelian principles, and introduces a table, collected from many different workers, of 4,856 families and 10,945 children, which demonstrates how nearly correct is the rule of inheritance—exceptions occurring only in thirty families (0.6 per cent.) and 100 children (0.9 per cent). He suggests that with improved technique this divergence might be even further reduced. The inheritance of blood groups is a most perfect example of the value of the law of inheritance as applied to man, and, apart from any biological interest, has fully justified its use in the determination of paternity. There is a most interesting chapter on the geographical and racial distribution of blood groups, a subject which is now attracting a great deal of widespread research, though so far with only provisional conclusions; it is a study which may well contribute to the solution of some of the deeper problems connected with the origin of man.

After a short account of the practice of transfusion there follows a discussion on the varieties of methods employed, and an attempt is made to explain some of the undesirable reactions and fatal results which occur unexpectedly after transfusion, and the precautions to be taken to prevent these occurrences. Group estimations should always be made, not only the interactions of receiver and donor which sometimes may give erroneous results if the serum of one or the other is feeble, but by typing both receiver and donor. The section on medico-legal aspects of blood groups discusses the determination of paternity, a subject which has received much practical study, especially in Germany, and also the detection of superfecundation and the diagnosis of blood stains. The last chapter is reserved for description of methods, and includes among others some good photomicrographs illustrating Thomsen's ingenious device for the determination of blood groups by using a standard mixture of blood cells A four-fifths and B one-fifth, so that with serum O$a\beta$ all the red cells will be agglutinated, with serum Aβ only one-fifth of the cells will be agglutinated, with serum Ba four-fifths, and with ABo none of the red cells will be agglutinated.

This is a most interesting and useful book. A translation into English would be welcomed by all English-speaking students and research workers.

THE ART OF PERCUSSION.

There are few things harder to learn in medicine than the art of percussion; indeed, an authority on pulmonary diseases once said that it had taken him fifteen years' continuous practice to master the technique with any degree of accuracy. This technique can only be learnt by examining the patient, but undoubtedly valuable hints can be picked up from the literature on the subject. We have just read with much interest a book by Dr. J. B. McDOUGALL on *Percussion of the Chest*,[2] a book which has been written with the object of pointing out the inestimable value of percussion correctly performed, as an aid to the diagnosis of diseases affecting the chest. The author states that the commonest error is to percuss too hard, thereby losing much valuable information of any morbid condition that may be present. His advice is to percuss gently, and he describes very clearly his technique and the methods by which he has learnt it. He gives a long account of the acoustic side of percussion, illustrating his points in terms of music, and describes the variations of the percussion note met with in pulmonary disease. His methods enable him to differentiate, by percussion alone, a serous pleural effusion from an empyema, even in the absence of oedema of the chest wall. The book is almost entirely concerned with the lungs—the percussion note of the heart being dealt with in a comparatively few lines. This is a pity, for the apex of the heart is really the most important surface marking of the chest, and its position plays a great part in the study of diseases of the lungs. The book, which is essentially one for those engaged in the teaching of medicine, is elegantly bound, but lacks an index. Its novel features are some rather heavy drawings and a bibliography, alphabetical in principle but not in detail.

MODERN PREVENTIVE MEDICINE.

In his book on the *Evolution of Preventive Medicine*, published in 1927 and reviewed in these columns at the time (December 10th, 1927, p. 1094), Sir ARTHUR NEWSHOLME traced the progress of the preventive idea from antiquity down to the dawn of the new era which revealed the role of the micro-organism in infection and opened the way to a system of prophylaxis based on sure knowledge of the causes of disease. There he rested temporarily from his labours, stating that the growth of scientific medicine since Pasteur had been enormous enough to demand a special volume which might follow. The special volume which has now happily appeared under the title *The Story of Modern Preventive Medicine*[3] forms a distinguished sequel to the earlier work. Though it includes a span of some seventy years only, by contrast with the centuries covered by its predecessor, it surveys an amount of patient research crowned by successful and salutary achievement which is unexampled in the history of medicine and perhaps of any science. The work of many observers in various countries on infectious diseases, together with the practical application of their numerous discoveries, has been brought within the compass of a book of moderate size in that lucid and informative manner which we have learned to expect from the writer.

After a note on Pasteur's early work, in the course of which he disproved the possibility of the spontaneous generation of life, reference is made to what is rightly called the first and greatest triumph of the application of the germ theory through the introduction by Lister of the antiseptic methods which are the foundation of modern surgery. Under the prevention of rabies a description is given of the saving of Joseph Meister by Pasteur, and it is shown how the present-day immunity of Britain is due to Mr. Walter Long's muzzling order, followed by overseas quarantine. The cure and prevention of diphtheria by current methods includes an account of the community immunization by means of the toxoid-antitoxin mixture. The results claimed in America are noted, but an attitude of caution is recommended. The view is expressed that it is too early as yet to give complete statistical proof of the communal protection afforded. The section on enteric fever recalls a number of historic outbreaks, the details of which it is pleasant to peruse in this convenient form. The various channels of infection are considered and the carrier problem is touched on. The louse-borne diseases, hookworm disease, plague, filariasis, and Texas fever are

[3] *The Story of Modern Preventive Medicine.* By Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. London: Bailliere, Tindall and Cox. 1929. (Cr. 8vo, pp. xii + 295, 9 figures. 18s net.)

reviewed in turn, and under malaria Sir Ronald Ross's factors are quoted by which the continuance of the disease in localities is determined. A postscript to the chapter on yellow fever records the fact that Noguchi's leptospira has ceased to be regarded as the causative parasite. A hopeful feeling is entertained of the prospect of the ultimate suppression of tuberculosis. With reduction of the opportunity of infection and increase in the capacity of resistance each successive crop of tuberculosis cases should be scantier than the one before.

Other topics in the book are ventilation, smoke, sunlight, occupation, housing, and the prevention of goitre, rickets, scurvy, beri-beri, and alcoholism. On these and kindred subjects the author's high position and long experience of the administrative field entitle him to speak with authority. His views will be read with interest and appreciation by all who are concerned with hygiene or the general welfare of the people.

DISEASES OF CHINA.

A SECOND edition of *The Diseases of China*[4] by Dr. JAMES L. MAXWELL has appeared. The first was published in 1911, the authors being Drs. W. H. Jefferys and J. L. Maxwell, but, the former having retired, Dr. Maxwell has undertaken the revision single-handed, and has had to rewrite the book almost completely. Since no one man can write authoritatively on both medicine and surgery, Dr. Maxwell has drawn freely on the medical literature sent to him as editor of *The China Medical Journal*, and has received material from all over China. This work aims at being of value chiefly to doctors in isolated situations, and it doubtless will be so, especially to the more recent comers who find themselves confronted with strange cases they never encountered before. The first chapter is an interesting summary of the conditions of practice in China as regards the methods of native "quacks," but the part dealing with modern scientific practice is written in too general a sense, and will give little help to those who turn to it for information about the professional and research facilities which are now available. The same remark applies to the chapter on "nosogeography," which only skims the subject, no doubt from lack of material, as there has never been any systematic attempt to study the geographical distribution of disease in China. Practitioners will look in vain for many points embodying the latest work on plague: all the forms of it are dealt with in ten pages, as against twenty-four for leprosy, which has no manifestations peculiar to China. Chinese diet is not mentioned, though it is worthy of consideration in the cause and treatment of various native disorders. Nevertheless, the volume contains much valuable information for the lonely doctor, who will find a good deal to stimulate thought in the right direction if he follows up the quoted work of Far Eastern pioneers. For there yet remain diseases in China not known elsewhere, and markedly so in the realm of parasitology, where there are etiological factors that call for research and further knowledge than is made available. While Dr. Maxwell's work is praiseworthy we think that in a future edition he might consider the advisability of entrusting some chapters to men, Chinese and others, who have specialized on various lines and whose published researches have shown they can be regarded as authorities. It contains no mention of public health work in China, or of the manner in which it has been found most expedient to administer it in dealing with local outbreaks of plague and cholera and with diseases like tuberculosis and trachoma that scourge the country.

The book is published in Shanghai and should have a wide sale in China. It is well illustrated, some of the photographs being startling in the way they show the length to which human afflictions can go. Though lacking in some respects it is important in showing that China is too large a place for safe generalization about its diseases: false conceptions have already arisen for want of a proper understanding. We yet await, for example, more detailed data about the incidence of malignant diseases and the information to be gathered from them.

"RACIAL HYGIENE."

To be of value a book should have something new, either of matter or manner; but, unfortunately, with one exception, Professor THURMAN B. RICE'S *Racial Hygiene*[5] has neither. The exception is the account of an investigation he himself made into the fertility of the socially inadequate. He ascertained (through a public dispensary) the size of family of 1,117 women who were so destitute, mainly through illness or defect, that they could only obtain medical students to attend them in childbirth. The details are remarkably interesting, especially in showing how early some of these women begin to add to the population.. The average size of family of those aged 35 was 6.2; of those at 40, 7.2; and at 41, 10.7. The last figure is probably too high to be representative, but the figure of 7.7 for all mothers over 35 years is almost exactly that tentatively arrived at by Mr. E. J. Lidbetter from his researches (unpublished) into the pedigrees and fertility of London paupers. By way of comparison Professor Rice obtained similar statistics from a maternity home used by a cultivated class. These mothers only achieved 2.2 children a head at and over the age of 35.

In other ways the book is very like all the other introductions to eugenics, though showing, perhaps, a little more common sense in sociology and a little more confusion between eugenics and hygiene. Like them, it quite fails to pass the crucial test of rendering the complexities of biology easy to understand; in fact, Professor Rice has obviously not mastered them himself. He shows a lack of comprehension of natural selection, and there are even gross errors in his descriptions of various vital processes. For example, on page 46 he implies that bi-parental inheritance *reduces* variation, and on page 48 et seq. he betrays an apparent complete ignorance of the X and Y chromosomes and their function in sex determination. Again, in chapter vii he confuses sex-limited with sex-linked characters, speaks of the female as the weaker sex, and attributes the high sex ratio at birth to the excessive mortality of *female* embryos. In fact, very many more males than females are conceived, while their pre-natal mortality is at least 60 per cent. higher.

Though a little happier when dealing with the sociology of the subject, Professor Rice perpetuates two common errors—first, that genius is linked with insanity, and secondly that France has a stationary population. Like most tyros, he considers "recessive" less harmful than "dominant" defects, and even recommends out-breeding as a cure—which would scatter the seeds of racial weakness throughout the normal population. In short, inaccuracy and superficiality are not redeemed by a Sunday school idealism, and they render the book most unsafe for the laymen for whom it is intended.

A FRENCH SURVEY OF PRACTICAL MEDICINE.

THEY order certain matters better in France, but it is not mere insular prejudice which compels us to say that the production of a medical annual is not one of them. The Annual Review of Practical Medicine,[6] compiled under the direction of Dr. CAMILLE LIAN, with a preface by Professor SERGENT, and now in its eighth year, contains material similar in all respects to that in the *Medical Annual* of this country, but falls far short of it in bulk, binding, and quality. There is, on the other hand—as, for example, in the plea that phthisical diabetics should no longer be left to their melancholy fate, but resolutely "set about" with insulin and artificial pneumothorax—an air of optimism in the whole book not equally conspicuous in the *Medical Annual*. It presents, moreover, in very handy form synopses of work recorded in the less well-known provincial French medical journals, in this respect differing wholly from the *Medical Annual*, and having a national rather than an international character.

On reading the summary-reviews we gain the impression that considerable advances have occurred in medical treatment. We note the wide possibilities of liver therapy in

[5] *Racial Hygiene.* By Thurman B. Rice, A.M., M.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1929. (Demy 8vo, pp. xiv + 376; 57 figures 18s. net.)

[6] *L'Année Médicale Pratique.* Publiée sous la direction de Dr. Camille Lian. Préface de M. le Professeur Emile Sergent. 8me année. Paris: R. Lépine. 1929. (4¼ × 7, pp. xx + 621.)

conditions of avitaminosis and dropsical states of all sorts. Surgery appears to have a place in the treatment of syringomyelia. The technique of oleothorax is given fully and the method is praised faintly. Induced malaria has been tried with interesting results in dementia praecox. Encephalitis and post-encephalitic states can be usefully combated with a course of intravenous acriflavine. The treatment of asthma is fully considered under the headings of local anaesthesia, ablation of the plexuses corresponding to the stellate ganglion, ephedrine, radiotherapy, and venesection. Very precise instructions are given as to the indications and technique of radiotherapy in angina pectoris. The outstanding article of the whole book is on the clinical uses of quinidine; in this the reviewers go so far as to say that all sufferers from auricular fibrillation should be subjected to quinidine therapy at the earliest possible time; provided embolic phenomena, cardiac decompensation, or bradycardia are not already present. They urge that a new chapter in cardiac prognosis could be written if quinidine were more widely used. The outbreak of dengue in Athens in 1928 is described very thoroughly by a Greek physician, whose article will be useful to future writers of medical textbooks. Abortive, hyperpyretic, relapsing, hypotensive, haemorrhagic, nervous and gastro-intestinal forms of dengue are recognized, and the complications include paralyses, cardiac failure, uraemia, gastro-enteritis, pleuropneumonia, and furunculosis.

Apart from the topics we have mentioned, this year-book contains several hundred summaries of French medical progress in all the branches of science, and for this fact alone we think it should accompany the *Medical Annual* into every library in this country.

NOTES ON BOOKS.

THE third or May number of the first volume of the new series of the *Annals of Medical History*[7] contains seven original articles on very various subjects, and, as usual, is generously illustrated. In the first article, on "Bath Olivers—doctor and biscuit," Dr. E. B. Krumbhaar describes the activities of William Oliver (1695–1764), not to be confused with another Bath doctor of the same name (1659–1716), who also wrote a book on the Bath waters. The portrait of the inventor of the biscuit forms the frontispiece of this instalment. Dr. Casey Wood writes on Lord Byron's physician, Julius Millingen, fortified by knowledge obtained from Edwin van Millingen, the son of his subject, and includes an account of Lord Byron's necropsy. Dr. W. G. Aitchison Robertson gives an account of "The Castle of Helth" and its author, Sir Thomas Elyot, whose portrait decorates the cover. Of Albrecht von Graefe, who died in 1870 at the early age of 42, Dr. F. H. Adler writes that in many of its departments ophthalmology has not advanced since his time, and that this shows how great the man was. The longest article, occupying about a third of the number, is on the history of Haitian medicine, by Lieut.-Colonel Robert P. Parsons of the United States Naval Medical Corps, who points out that what was a hotbed of disease has within ten years been transformed into a relatively healthy land, which compares favourably in sanitation with any place in the tropics; this is largely due to the directing genius of Admiral E. R. Stitt, surgeon-general of the United States Navy. Dr. F. S. Hammett writes on the anatomical knowledge of the ancient Hindus, and Dr. E. W. Gudger on some early and late illustrations of comparative osteology.

Dr. GUY BOUSFIELD's little work on *The Schick Test and Diphtheria and Scarlet Fever Immunisation*[8] contains a full and clear explanation of active immunization against diphtheria and scarlet fever, with details as to technique. Allied subjects are discussed, such as the occurrence of diphtheria among apparently immune persons, the immunization of schools and control of epidemics, the institution of a clinic for wholesale immunization, and an account of the accidents, some of which were fatal, attending diphtheria prophylactic measures with advice as to their prevention. The chapter on scarlet fever contains a description of the Dick test and the method of active immunization against the disease. A list of twenty references is appended, all but one being to English or American articles.

[8] *A Practical Guide to the Schick Test and Diphtheria and Scarlet Fever Immunisation.* By Guy Bousfield, M.B., B.S. London: J. and A. Churchill. 1929. (Post 8vo, pp. 71; 4 plates. 5s. net.)

In his volume on *The Heart*, in the eleventh edition of *Quain's Elements of Anatomy*,[9] Professor WALMSLEY gives a thorough-going account of the comparative anatomy, development, and structure of that organ, with a number of satisfactory illustrations. Abundant references to the literature of the subject are given, and many interesting details of the history of the anatomical study of the heart are to be found in the text. Professor Walmsley has a clear style, and is to be congratulated on the success with which he has described the anatomy of the heart. This book should be in the hands of all anatomists and senior students of anatomy.

The clinician has offered to him in the work on the cardiogram in the left lateral position,[10] by PACHON and FABRE, another instrumental method for studying cardio-vascular disease. The authors contend that the capacity of the heart for work can be deduced from comparisons of the apical cardiac impulses in a given posture, as recorded graphically, with supposedly normal impulses. It being, however, admitted that curves obtained from points but slightly removed from the apex are quite unlike apical curves, the validity of the method is in all cases at least conditioned by the possibilty of localizing the apex beat, even if the basic principle of a quantitative relationship between impulse and cardiac output is accepted.

The thirty-seventh edition of *The Annual Charities Register and Digest*[11] is a work indispensable to those engaged in charitable and good deeds, and anxious to do the best that can be done with their money. Its object is to set out the many ways in which distress may be relieved by recourse to hospitals, homes, special institutions, and so forth, and gives full details of what may be done in these directions. The contents of this *Register* are classified under such headings as relief in affliction, relief in sickness, relief in permanent or temporary distress, reformatory relief, and the like; there is an appendix, too, with a deal of useful information about benevolent institutions, friendly societies, trade societies, and many other such matters. The book ends with a very full index, and may be most warmly recommended to all charitable workers who are not already well acquainted with it—if, indeed, any such exist.

[9] *Quain's Elements of Anatomy.* Vol. IV, Part III: *The Heart.* By Thomas Walmsley, M.D. Eleventh edition. London: Longmans, Green and Co. 1929. (Roy. 8vo, pp. vii + 152; 84 figures. 16s. net.)

[10] *Le Cardiogramme de Décubitus Latéral Gauche en Clinique.* Par V. Pachon et Roger Fabre. Paris: G. Doin et Cie. 1929. (6¼ × 9½, pp. 87; 36 figures. 20 fr.)

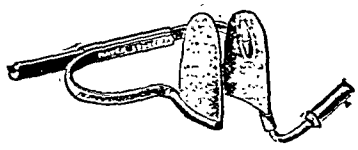
PREPARATIONS AND APPLIANCES.

AN ILLUMINATED NASAL SPECULUM.

MR. JOHN E. G. MCGIBBON, M.B., B.S., D.L.O. (Liverpool), writes: The accompanying illustration shows a simple electrically illuminated nasal speculum. The light-carrier is of the Jackson type, set at an angle through the blade of the speculum,



and can be removed for cleansing. The instrument is useful for bedside examination when it is difficult to obtain a satisfactory light. The same principle could be applied to the Thudichum type of speculum. The instrument here described has been made for me by Messrs. Mayer and Phelps.

A LABOUR-SAVING DEVICE FOR URINE EXAMINATION.

Dr. G. RAMSEY PHILLIPS (London) writes: Disliking the task of filling test-tubes direct from a pot and having to wash up a greater number of pieces than necessary, I have had a battery hydrometer adapted for urine. This instrument, illustrated

herewith, will pick up a specimen from any kind of vessel, show the specific gravity, and fill a test-tube without spill or mess. The usual cleansing of pipette, urinometer, and trial jar is reduced to the one simple operation of drawing in clean water and squirting it out again. The device may be obtained from Messrs. A. Charles King, Ltd., 34, Devonshire Street, W.1.

British Medical Journal.

SATURDAY, JULY 6TH, 1929.

PROGNOSIS IN MYOCARDIAL DISEASE.

THE St. Cyres Lecture on diseases of the myocardium, delivered by Dr. R. O. Moon and published in our present issue, deals with as difficult a subject as may be found in cardiology, perhaps in the whole of medicine. We are accustomed to hear that knowledge of prognosis in cardiac disease has advanced considerably in late years, but Dr. Moon shows that the essential facts were not unknown to writers of the early nineteenth century. The introduction of percussion and auscultation of the chest, of all manner of new diagnostic instruments, each credited by its devotees with unprecedented powers, may be blamed for creating obscurity where there was once clarity. It must be admitted, however, that the older writers, such as Corvisart and Stokes, though perhaps possessed of the key to cardiac pathology, understood so little of the morbid anatomy of the myocardium and the functions of the circulation that they lacked the lock in which to fit it. The expectation that microscopic examination would elucidate the nature of the changes in a diseased heart has not altogether been fulfilled. Cardiac pathologists feel, indeed, that such examination has misled those who, finding the hypertrophied myocardium histologically normal, have ascribed the enlargement entirely to physiological compensation for valvular defect. Similarly, the histological characteristics of the diseased myocardium described so fully by Dr. Moon are found only in a small proportion of cases; in most diseased hearts the changes found on microscopic examination are small and inconstant.

The cadaver having failed, then, to yield its secret, one turns to the living subject, and asks how the state of the myocardium is to be judged. The question would appear to be simple and likely to yield a simple answer, even when due weight is given to the complexity of the circulatory mechanism and our present incomplete analysis of it. Looked at from one point of view, the function of the circulation is to control the metabolism of cells in proximity to the smallest blood vessels, and at first sight it would seem that a more or less pronounced failure to respond to the increased demand when the metabolic rate of these cells is augmented might be taken as an indication of myocardial damage. Nothing, apparently, could be simpler than to note the patient's response to exercise; increase in the respiration rate would show that deficiency in the circulatory function is being made good by one of those allied mechanisms whose importance and multiplicity are now being realized; similarly, an increased pulse rate would suggest—perhaps with less certainty, in view of the variable excitability of the vagal and allied centres—that a raised mean arterial pressure has been called to the aid of the peripheral circulation. Unfortunately, however, these responses alone do not sufficiently indicate the capacity of the myocardium for work, the state of the other organs, the tone of the patient's muscles, and his physiological responses, all being variable factors.

A prognosis in heart disease, as in other diseases, may be based on the study of properly accumulated statistical data. If large numbers of cases correctly classified are followed over a period of years, then the expectation of life and activity of any new patients should admit of approximate estimation. Statistics on these lines are being prepared; the problem lies in the allocation of the given case to its proper class. A study of etiology is important, because the prognosis of myocardial disease is to some extent determined by its cause. Equally important is it to know how seriously the muscle is damaged, the present tendency being to lay special emphasis on one tangible sign, and to base an estimate on its prominence. Thus some clinicians look to the size of the heart, some (especially in America) to the form of the T wave in the electro-cardiogram, others to the results of an exercise tolerance test.

During the past century the number and loudness of intracardial murmurs, and the nature of the heart sounds, served as a guide to the patient's future, on the gratuitous assumption that the heart must yield its secret to a well-manipulated stethoscope. Clinicians who had devoted many years of patient study to classifying heart sounds tended to base prognosis on the material yielded by this method of investigation and to teach their pupils to do the same. It would be going too far to affirm that the stethoscope should not be used at all in examining the heart; it is, however, correct to say that the information the stethoscope affords is small compared with that derived from more general considerations—in short, that all auscultatory signs should be interpreted with scepticism. If heart murmurs are to guide us at all it is in grouping our cases for statistical purposes. The classical apical and basal diastolic murmurs afford, according to available statistical data, good evidence of valvular disease, and point, therefore, to the existence of corresponding myocardial damage. The diagnosis of valvular lesions from apical and basal systolic murmurs is subject, however, to two fallacies: first, basal systolic murmurs are often absent in cases of mitral stenosis with sclerosed cusps, notwithstanding the considerable regurgitation which is bound to take place with each ventricular contraction; secondly, as Grant showed a few years ago, patients whose only cardiac abnormality is the apical systolic murmur do not tend to develop disease of the circulation sooner than normal subjects. The systolic murmur is neither direct nor indirect evidence of myocarditis, and unless we know there is myocardial damage we must hesitate to make other than an optimistic prognosis. A like scepticism should be applied to the evidence given by the cardiac rhythm, which at one time was picked out and studied as a unique criterion of myocardial efficiency. Interest in arrhythmias absorbed the attention of cardiologists for many years, and inspired the epoch-making work of Sir Thomas Lewis on conduction of the heart muscle; but though a great deal is now known about cardiac irregularities and their differentiation by simple clinical methods, faith in their prognostic significance has waned.

The evidence afforded by the size of the heart, especially if correlated with the results of the exercise tolerance test, is often valuable both in diagnosis and prognosis. It is important, however, to realize that in some obscure but common forms of myocarditis found in advanced life, the weight of the heart may be normal, and the clinician must then seek other signs for his guidance. An analysis of Dr. Moon's ten points shows that the less equivocal of these signs are not to be elicited merely from an examination of the chest; we have to do violence to man's analysis-loving intellect, and, considering as

best we can the body as a whole, ask, Does it work or does it not? We cannot but agree with Dr. Moon's statement that "even when there is no doubt about the existence of myocardial degeneration it is still extremely difficult to make a certain prognosis." Even the statistical method may avail little; experience has shown too many cases of myocardial disease which, though apparently similar, have followed entirely different courses.

HYDATID DISEASE.

HYDATID infestation presents many problems of interest to the surgeon and pathologist alike. The parasite may exist but does not develop outside the body of a host, and the biphasic life-cycle occurs partly in the intestine of the dog and partly in the parenchymatous tissues of an intermediate host, usually one of the herbivora. Man may also act as an intermediate host, but in this case the cycle is broken. The act of infestation of man is, in the nature of the case, definitive. As a witty French writer has said, the human hydatid is "sans avenir, sans espoir." Many of the phenomena of hydatid development found especially in man may be related to the interruption in the normal cycle of evolution. The formation of daughter and granddaughter cysts, so common in human hydatid as distinguished from that of the herbivora, for instance, may be an attempt to perpetuate the active elements of the parasite, pent up in a longer-lived intermediate host.

We publish this week at page 5 a paper by Professor Carmalt-Jones, recounting his observations on hydatid disease in New Zealand during the last ten years. In New Zealand, although the close association of man with sheep and dogs makes infection possible, the incidence of hydatid disease is not high. It is estimated that about 150 new cases occur each year, probably about 1 in 10,000 of the total population. In Great Britain the disease is rare, and cases of hydatids are curiosities. In New Zealand, judging from Professor Carmalt-Jones's experience, it is the element of surprise that dominates the picture, and this in spite of the teaching that in hydatid-infested countries the practitioner should think always of hydatid.

The mode of infection is by the alimentary tract and portal vein, so that the liver shows the highest incidence. The lung is the next commonest seat when the embryo is caught in the lung capillaries after passing through the right side of the heart. The embryo may, however, negotiate the lesser circulation and left heart, and become lodged in any organ or tissue of the body. In its site of lodgement it becomes surrounded by a fibrous capsule formed from the tissues of the host. No specific symptoms of hydatid disease occur, for the hydatid is in effect a foreign body; and when situated in an indifferent tissue, apart from accidents, it may show a remarkable degree of latency, extending often over years. But it is a foreign body capable of growth, so that symptoms due to pressure usually occur sooner or later. Often the vitality of the hydatid becomes exhausted, the cyst contents dry up, and are partly absorbed; the fibrous capsule may then have lime salts deposited in it, and the parasite be discovered as a stony mass only at a post-mortem examination. Accidents may happen both to host and to parasite. Of the former the most important is the erosion of a blood vessel, usually a vein, during growth of the cyst, followed by severe haemorrhage. Small leakages from the cyst may produce a state of sensitization in the host, so that rupture may be followed by severe symptoms of anaphylactic shock. Dévé of Rouen has recorded an instance of a child dying eight hours after a successful operation for hydatid, in which no explanation could be found other than shock produced by spilling hydatid fluid at operation on a patient previously sensitized. Accidents to the parasite itself are usually suppuration or rupture, both following trauma of greater or less degree. A suppurating hydatid cyst produces symptoms of abscess in the organ in which it is situated and the course is similar. Rupture may occur into a serous cavity, bronchus, blood vessel, or gland duct such as the ureter. A diagnosis may be made from hydatid cysts passed per urethram, and a doubtful pulmonary case may be cleared up by the patient coughing up the cyst. Rupture of the cyst has a special practical interest, for in some circumstances a form of development takes place differing from the cycle of dog to intermediate host and back. Tiny daughter cysts, and even the scolices or buds formed in the brood-capsules of the cysts, are capable of growing when implanted in a new tissue. In this way secondary infection of the peritoneal, pleural, or pericardial cavity may take place through rupture; and of the incisional wound and adjacent tissues by spilling of hydatid material at operation when imperfect technique is used. Further, rupture into a blood vessel or into the heart may lead not only to embolism of hydatid material, but a secondary echinococcosis from development of embryonic hydatid material at the site of embolus.

The symptoms of hydatid disease are thus protean and may resemble those produced by any other foreign body in the tissue affected. Nevertheless, in the symbiosis of host and parasite there are interactions between the two. The hydatid obtains nourishment by absorption from the host's tissue fluids and may also attract infecting germs which produce suppuration. The host responds to the presence of the hydatid by elaborating substances which can be demonstrated by appropriate biochemical procedures. In common with other helminths, the *Taenia echinococcus* evokes an eosinophilia. This has been shown to occur in the blood and around the site of the growing hydatid cyst in experimentally infected animals. Gross eosinophilia is a recognized phenomenon during the early stages of infection with *Bilharzia* and *Fasciola*, and it is likely that a similar pronounced eosinophilia in the circulating blood occurs during the invasion period of hydatid infection; but so far as we know no case has been recorded at this stage, probably because the invasion is insidious. As long ago as 1906 Welsh and Barling, using the absolute count of eosinophil leucocytes rather than the percentage, found that 50 per cent. of cases of hydatid before operation had 500 to 2,500 eosinophil leucocytes per cubic millimetre. In Professor Carmalt-Jones's paper the less satisfactory method of recording the percentage is given, and he states that only 35 per cent. of cases in a series observed had an eosinophilia of more than 5 per cent. It is advisable to estimate the absolute eosinophil count, which is normally little over 200 per cubic millimetre. We think it necessary to emphasize this point, since an eosinophilia may be a valuable aid to diagnosis in this country, where laboratories have not the specific antigen to carry out the tests by complement fixation and precipitins. These latter tests, however, in routine use, have won a high regard for their accuracy in determining the presence of hydatid in doubtful cases, and a positive result is diagnostic. A sensitization of the host usually occurs, so that intradermal injection of sterile hydatid

fluid produces an erythema and induration at the site of injection in a large percentage of patients with hydatid disease. Since the sterile antigen can be put up in glass phials and kept for many months with full potency, the use of the Casoni intradermal skin test is likely to be of much value where hydatid only rarely comes into consideration. Professor Carmalt-Jones has been struck by the association of hydatid disease and haemorrhage, and suggests that the bleeding may be in some cases a manifestation of sensitization. This is worthy of note, and should be followed up by those who have an opportunity of observing a series of cases.

As the hydatid is not only a foreign body, but is also by its growth and possible complications fraught with danger to the host, removal by surgery is the best treatment. The mode of attack will, of course, vary with the site of the cyst, and in defining this radiography is often invaluable. The special surgical indications are to prevent infection of the wound and surrounding tissues by embryonic hydatid material, and to control haemorrhage from the fibrous capsule which surrounds the cyst and which is part of the host's body. The former indication is met by the injection of formalin in sufficient amount to bring about a 1 per cent. solution in the contents of the cyst before it is incised. This kills the embryonic scolices and sterilizes the contents. In addition, the wound and its surroundings should be efficiently packed off to prevent spilling of hydatid material during evacuation. The fibrous capsule must be handled gently. It may under certain conditions be filled with normal saline solution, closed by suture and allowed to drop back from the wound, but it is safer to close it and fix it under the wound so that drainage may be instituted later if the indication should arise. In the presence of complications, drainage may be required; but convalescence is thereby delayed and care is needed to prevent secondary infection. In some cases a portion of the fibrous adventitia may be taken away, and in calcified cysts the whole capsule has been removed successfully at times. It is recommended that a cubic centimetre of adrenaline solution should be injected into the patient ten minutes before operation, if there is any reason to fear anaphylactic shock.

In the countries in which it is endemic, cases of hydatid disease have many features of interest and surprise. They are, however, a cause of much anxiety in those who are called on to deal with them. As the public becomes more instructed in the mode of infection and in the methods of prevention, it is to be expected that human hydatid infestation will disappear.

TOXOID AND TOXIN-ANTITOXIN IN DIPHTHERIA IMMUNIZATION.

IN methods of vaccination or immunization against disease the main requirements are that the materials used shall not cause danger to life, that they shall produce sufficient immunity, and that they shall not cause severe reactions. All the ordinary preparations such as the typhoid vaccines, plague vaccine, and the prophylactics used to immunize against diphtheria and scarlet fever meet the first requirement; when properly made and tested, they do not endanger the life of a person vaccinated. An interesting article by G. F. and G. H. Dick[1] raises the relative importance of the other two requirements. These two workers set out to compare the immunizing activity of toxoid (Ramon's "anatoxine") and the 0.1 L+ toxin-antitoxin mixture used in U.S.A., by giving to each member of a group of 100 individuals five doses of the mixture, and, to each of a second group of 100, three doses of toxoid. Six to twelve weeks later, 82 of the former group and 94 of the latter were negative to the Schick test. The groups probably did not consist of exactly comparable individuals, and the difference between 82 per cent. and 94 per cent. is not highly significant; the results, therefore, do not show much superiority of the toxoid, though, in view of the fact that each cubic centimetre of toxoid contains much more—perhaps thirty times as much—of the original filtrate from the broth culture of the diphtheria bacillus, it would not have surprised immunologists had they done so. Toxoid, of course, is no new product. Löwenstein in 1914[2] described work he had carried out five or ten years earlier on the formalinization of tetanus toxin. Glenny and Sudmersen in 1921[3] showed that diphtheria toxoid—that is, toxin formalinized until it was non-toxic to guinea-pigs—could produce high immunity, and Glenny and Hopkins referred (1923)[4] to the immunization of horses with toxoid some fifteen years earlier. In 1923 Ramon[5] reported that he proposed to test whether toxoid could cause the production of antitoxin, and in 1924[6] he reported results showing high immunity, and minted the word "anatoxine" for "toxoid." The obvious suggestion that toxoid would be the best immunizing agent for human beings occurred to immunologists[7] in 1923; in the same year Schroder and Park[8] had already used a "deteriorated toxin (toxoid)"—and in 1924 a formalinized toxoid—for the immunization of human beings. In 1924 O'Brien[9] reported the immunization of human beings with toxoid prepared with formalin. Ramon and his French colleagues immunized human beings with toxoid in 1924[6] and, largely owing to Ramon's vigorous and able advocacy, it is now employed exclusively in France and the greater part of Europe and in Canada. The Dicks refer to the impression in America that toxoid is apt to cause severe reactions, particularly in adolescents and adults. Park[10] has used toxoid on a fairly extensive scale from 1924 onwards, but we note that in a large amount of forceful propaganda in the present campaign in New York, aimed at the eradication of diphtheria within the next decade, the use of toxin-antitoxin mixture is urged and toxoid is scarcely mentioned. It may be that Park gives first place to the mixture because of the tendency of toxoid to cause reactions. Toxoid has apparently been tried cautiously by a few workers in England since 1924. Severe reactions are recorded by Nash[11] in adults, though none occurred in a small group of children. It may be that reactions of this kind have disappointed the earlier hopes and prevented the adoption of toxoid in Britain. Though the full tables are not given in the article by the Drs. Dick, they point out that 9 patients in a group of 144 suffered severe reactions, generally with local pain, temperatures of 102° F. to 104° F., malaise, etc. In 4 of the 9 the course of three injections was not completed, presumably owing to the severity of the previous reactions. We think that the average British physician accustomed to the toxoid-antitoxin mixture would be perturbed if a similar percentage of his nurses had to go off duty during immunization. A preparation of toxoid has been on the market in England for some time without apparently winning over those medical men who have confidence in the toxoid-antitoxin mixture commonly used. It almost appears that medical

officers of health and the physicians in charge of isolation hospitals, who carry out routine immunization of their staff—with the resulting abolition of diphtheria—have found that it is possible by the use of the less potent toxoid-antitoxin to obtain satisfactory immunity in a reasonable time without the risk of severe reactions. Most immunologists would agree that toxoid or concentrated toxoid possesses high immunizing power and would be used exclusively if it could be freed entirely from the constituents apt to cause troublesome reactions. It may be that eventually the use of toxoid or concentrated toxoid will become the universal method of immunization of children, while toxoid-antitoxin floccules or toxoid-antitoxin mixture will be kept for adults. Progress marches slowly in England, for medical investigators have a full—the eager research worker may be inclined to say "overfull"—sense of responsibility, and try the new thing with the greatest caution.

TEACHING SURGERY BY THE SOUND-FILM.

THOSE attending the summer meeting of the Section of Urology of the Royal Society of Medicine, on June 27th, witnessed what may well prove to be an important new departure in the instruction of students in urological and other operations. Three cinematographic films were projected illustrating respectively the procedure of suprapubic prostatectomy, litholapaxy, and internal urethrotomy, in all of which the operating surgeon was Sir John Thomson-Walker. The film illustrating urethrotomy was accompanied by a synchronized gramophone record in which the operating surgeon explained in a conversational way, as though he were commenting to a group of students, the use and handling of the instruments. This is almost, as Mr. Swift Joly remarked from the chair, the first attempt to show these operations by cinematographic means directly; sketches have been made before, and very ingeniously contrived so as to give a sequence to the film picture, but in this most recent innovation the cinematographic operator has been in attendance from the administration of the anaesthetic right through to the removal of the patient from the theatre. The film illustrating the prostatectomy began with the patient's case sheets, showing the history and the results of the examination, then proceeded to record the preparation of the patient, the passing of the catheter, and subsequently the making of the incision, the enucleation of the prostate, the exposure of the bladder base and prostatic bed, all bringing out with excellent clearness and on a large scale every movement of the surgeon's hands or instruments; then there followed the toilet of the internal meatus, the placing in position of the drainage tube, the repair of the abdominal wall, and the dressing of the wound, finishing with the removal of the patient on the inclined plane trolley. A demonstration was also given of the removed prostate, which was sectioned before the camera. The second operation to be shown on the screen was Bigelow's procedure of litholapaxy. Here one saw the washing of the bladder with boric acid and the introduction of the lithotrite; by an ingenious diagrammatic interpolation, rather after the manner of the quick change of the entertainment screen, it was shown how the stone was grasped and crushed in the jaws of the lithotrite, and the fragments evacuated by suction. In the third film, showing internal urethrotomy, performed for stricture of the urethra when the case was unsuitable for dilatation or when dilatation had failed, the operating surgeon, as already stated, became the narrator, and it was certainly an advantage to listen to his voice explaining the manipulations as they took place rather than to depend upon a title film at intervals. In reply to some congratulatory comments from those present, Sir John Thomson-Walker said that his attention was drawn to this method by his colleague Mr. Cecil Wakeley, whose enthusiasm had swept him (Sir John) past his first doubts and hesitations. Accustomed as he was when operating to rely only on one group of workers, he found himself in this instance compelled to consider two groups, and, when the sound record was added, three. The first group was the staff of the urological department of King's College Hospital, who were helpful as ever, and withstood the glare and heat of the "Hollywood conditions" with their usual composure. The second group consisted of those engaged on the motion picture record—namely, the medical department of Kodak Limited, of whose technical efficiency he could not speak too highly. The outcome of this combined work made it possible to see the operation on the film much more comfortably and to better purpose than in the theatre itself. When it was decided to make a sound-record a third group of assistants came forward, in the shape of members of the staff of "His Master's Voice" Gramophone Company, and they, too, had done their work exceedingly well. Sir John Thomson-Walker added that the procedures shown were those in general use, with possibly a few personal variations. The purpose of the film, which was quite experimental, was merely to indicate the value of the moving picture, perhaps accompanied by sound production, in medical education. It seemed to him to offer advantages in teaching in the schools. It was impossible to show every student every sort of case and every sort of operation, but the student could quite well assimilate half a dozen film operations in an afternoon. Other advantages, not mentioned on this occasion by Sir John Thomson-Walker, are the possibility of repeating the projection indefinitely until every detail becomes fixed in the mind, and also the possibility of stopping the film for closer examination at any point.

BRAIN AND MIND.

THE sciences of neurology and of psychology are admittedly still too wide apart, and every attempt made to correlate their findings—and this need not entail denial of the unique province of either—is to be welcomed. In *The Matrix of the Mind*,[1] Professors Frederic Wood Jones and Stanley Porteus have endeavoured to bridge the gap. The first forty or so chapters, which deal mainly with the developmental story of the brain, are contributed by Professor Wood Jones, and the remaining chapters, on the evolution of human behaviour, are the work of his colleague. Professor Wood Jones has a captivating style, and it is refreshing to read his account of cerebral development throughout the animal series. He has a flair for memorable phrases, and the headings of his chapters bear witness to his originality of expression. "Intuition and Panache," "Mistakes in Brain Building," "The Corpus Striatum and its Private Path," "What the Cortex cannot do," will afford some indication of his method of approach. Moreover, the raciness of his style sacrifices nothing to scientific accuracy: rather are the salient features of his account brought into greater relief and impressed upon the memory. He begins by discussing the idea of division of labour, and demonstrates the beautiful gradations which occur in the work of specialization. He describes the beginning of specialization in the common hydra. "When specialization is complete the single cell of dual function becomes the dual cells of single function. The one cell retains sensation and remains upon the surface, the other retains mobility and is buried beneath the surface." This is the starting point of Professor Wood Jones's description of what he terms the "external" and the "internal" nervous system. He discusses also the ancient kinship between the central nervous system and the skin,

[1] *The Matrix of the Mind*. By Frederic Wood Jones, F.R.S., and Stanley D. Porteus. London: E. Arnold and Co. 1929. (21s. net.)

which may justify the saying that beauty is only skin deep, but only when the matter is regarded rightly, for "it is as deep as the central nervous system." This discussion of the relationship of appearance and behaviour is original and arresting. There is an interesting account of the influence of one set of cells on another in the course of development, termed by the author "cytoclesis"; and his description of the mistakes in brain building in the invertebrates is singularly graphic. "To become a blood-sucker is to become a failure. Phylogenetic senility comes with the specialization of blood sucking. Phylogenetic death is sure to follow. Here, then, is an end to the progress in brain building among the invertebrates. Faced with the awful problem of the alternatives of intellectual advance accompanied by the certainty of starvation, and intellectual stagnation accompanied by the ability of enjoying a good square meal, they must perforce elect the latter if they are to live. The invertebrates made a fatal mistake when they started to build their brains around the oesophagus. Their attempt to develop big brains was a failure, it resulted in inevitable starvation. Another start must be made." This other start was the vertebrate's start, and Professor Wood Jones's narrative of it, which occupies his remaining pages, leaves nothing to be desired. Professor Porteus carries the story to the psychological realm in strict continuity with the preceding chapters, but necessarily, the difficulties being such, this part of the book is less satisfactory. The problems of consciousness and memory are well treated, though with perhaps something less than fairness to the concepts of psycho-analysis. Much of the difficulty inherent in the task that Professor Porteus has set himself is terminological, and when coming across such phrases as "a kind of consciousness not typically human" and "flashes of awareness" one feels the need for some such terminology as has been adumbrated recently by von Monakow.

THROMBO-ANGIITIS OBLITERANS.

THE morbid anatomy of thrombo-angiitis obliterans was first described accurately in 1879, though from examination of one case only, by von Winiwarter, who incriminated excessive smoking as a causal factor. Special attention was directed to it in New York by L. Buerger, who insisted on its racial incidence, and in London by Parkes Weber. A recent Mayo Clinic monograph[1] gives a complete account of the disease, based on observation of over 300 cases and a thorough review of the literature. The cases were observed at the Mayo Clinic from 1922 to 1927 inclusive, and each year the number recognized increased so that finally this disease accounted for 0.25 of all male admissions. Rather more than half the patients were Hebrews, but the incidence in Gentiles is increasing. The authors of this monograph regard abuse of tobacco as possibly a contributory factor, but not as primarily responsible; they consider that, though proof is still lacking, there is much evidence pointing to an infective origin. The average duration of thrombo-angiitis obliterans is five years. It begins with intermittent claudication due to anoxaemia; then follow postural changes, redness or pallor on dependency or elevation, and then pain, quite distinct from that of claudication, when the patient is at rest; lastly trophic lesions—ulceration and gangrene—supervene. But the clinical picture varies, and different types of the disease are described with an analysis of the symptoms. In two cases only was there reason to suspect coronary thrombosis, and it is remarkable that fatal pulmonary embolism never occurred, thus contrasting with post-operative phlebitis. With earlier diagnosis and treatment the prognosis is regarded in a more optimistic light than formerly. Special methods of investigating the disease employed by the authors include estimation of the rate of heat elimination, of the surface temperature, and of the vasomotor condition in the extremities. Treatment naturally depends on the stage of the condition. Prophylactic and other medical measures, such as radiant heat and non-specific protein shock therapy, are described; and the indications and results of surgical procedures, including sympathetic neurectomy, are passed in review. The authors note that all kinds of treatment were less effective in Hebrews than in Gentiles.

FUMES FROM ARTIFICIAL SILK WORKS.

IN our issue of June 1st (p. 1008) we referred to the risks to the workers from carbon bisulphide and hydrogen sulphide in the artificial silk industry by the viscose process. What was there said receives confirmation in a report of the chief inspector of alkali, etc., works.[1] As the title indicates, Dr. Lewis Bailey is concerned much more with complaints made from the outside than from the inside of the factory, and, as he shows, these complaints are serious. While absolving the industry from causing injury to the health of the community, he says the air from these works "is capable of being distinctly unpleasant" and of interfering with "the amenities of everyday life." The report is sadly unconvincing. Beyond calling for neutralization of free acids in dealing with the works effluents, little action seems to have been taken. Phrases such as "in the hope that," "has not been lost sight of," "more work is still needed," "certain other constituents," "to some extent," "it is possible that they could be," "should be effected," occur in nearly every paragraph, showing how far from solution the authorities are. We can pride ourselves, though, on the fact that "the works in England compare favourably with those in Germany."

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE eighty-eighth annual meeting of the Royal Medico-Psychological Association is to be held, under the presidency of Dr. Nathan Raw, on July 10th, 11th, and 12th, on the first day at the Westminster City Hall, where a civic welcome will be given by the Mayor of Westminster, and on the succeeding days at the British Medical Association House, Tavistock Square. In addition to the presidential address and several independent papers a discussion is to take place on the last day of the meeting on the report of the Mental Deficiency Committee (the joint committee of the Board of Education and the Board of Control), including, "if available," Part III of the report, on the mentally defective adult. Dr. A. F. Tredgold will open this discussion. Another paper, to be followed by discussion, is on the modern approach to the problem of the admission of mental patients to in-patient treatment, by Dr. J. R. Lord. During the meeting it is proposed to elect as honorary members of the Association Professor Pavlov of Leningrad, Sir Charles Sherrington of Oxford, and Professor Eugenio Tanzi of Florence.

THE late Lord Revelstoke, in addition to his gift of £100,000 to King Edward's Hospital Fund for London, of which he was treasurer, has left £50,000 to Guy's Hospital, and £25,000 to St. Mary's Hospital Medical School.

THE annual report of the British Science Guild announces that the Norman Lockyer Lecture for 1929 will be given on November 19th, in the Goldsmiths' Hall, by Sir Walter Fletcher, M.D., F.R.S., whose subject will be "Certain aspects of medical research and their applications."

THE CANCER CAMPAIGN IN YORKSHIRE.

RESEARCH AT LEEDS UNIVERSITY.

LORD MOYNIHAN, chairman of the Yorkshire Council of the British Empire Cancer Campaign, in introducing the report for 1928–29, stresses the need for research on the powers and properties of radium in order that this agent might be used to the best advantage.

"It is now certain," he writes, "that in radium we have a weapon of the greatest value in our attack upon cancer. But it is a two-edged weapon, and though immense good has resulted, and will increasingly result, harm can be done, and has been done, by its improper use. It is, therefore, essential that until both the healing and the harmful properties of radium are much better understood than they are now, the greatest care in its use, and the most accurate control and supervision of all cases, is required. The widespread use of radium by inexperienced persons is therefore to be most strongly deprecated. It would be a great advantage if for some time many of the more serious cases to be treated could be housed under one roof, under the care of men trained, and training themselves, in the knowledge of radium and all its physical and therapeutic powers. If some generous donor could be found to create, and perhaps endow, a Yorkshire radium institute to which sufferers from cancer could be admitted from all parts of the country, for both in-patient and out-patient treatment, he would be a true benefactor to mankind."

Experimental Hyperplasia.

The report presented by the director, Professor R. D. Passey, on the work of the department of experimental pathology and cancer research, University of Leeds, which is conducted under the auspices of the Yorkshire Council of the Campaign, records further progress in the investigation by Dr. J. S. Young on the part played by physico-chemical factors in the genesis of proliferation in the alveolar epithelium of the rabbit's lung. Proceeding from the observation mentioned in the previous report, that such proliferation can be produced by the intrapleural injection of an emulsion of olive oil and bile salts, it has been shown that bile salts are equally effective when exhibited in emulsion in a non-saponifiable medium, thus dispelling any doubt that the proliferation was induced by the direct action of the bile salts on the parent cells. The chemical and physical complexity of this reagent, however, made it desirable to conduct investigations, using simpler reagents, in order to discover whether cellular hyperplasia was caused by the chemical nature of the cells or their physical properties. The experiments, in general terms, resolved themselves into an attempt to analyse the effects of altering the environment of the endothelium covering the visceral pleura and of the epithelium lining the marginal alveoli by the intrapleural injection of simpler substances, and observations made on eleven salts have afforded evidence in favour of the view that physical factors play an important part in promoting hyperplasia in the alveolar epithelium of the rabbit's lung. That the chemical nature of the electrolytes also plays some part is suggested by the fact that their biological behaviour tends to harmonize with the classification of their cations in the periodic table; in other words, that the biological properties of a metal may, just as its chemical reactions, be governed in some degree by its atomic weight. It has been shown, furthermore, that groups of electrolytes, possessing monovalent, bivalent, and trivalent cations respectively, produce increasing manifestations of cellular proliferation as the valency of the cation increases, a confirmation of Loeb's valency rule with reference to the effect exercised by neutral salts upon certain physical properties of proteins—namely, osmotic pressure and viscosity of protein solutions and the degree of swelling of gels—when the hydrogen-ion concentration lies on the alkaline side of the iso-electric points of the proteins concerned.

Following these investigations preliminary observations have been made which promise to bear on the principles of tissue susceptibility and tissue immunity. The intrapleural injection of 5 c.cm. of a three-quarter normal solution of strontium chloride produces epithelial proliferation which attains a maximum on the third or fourth day, and during the next four days undergoes involution. This involution, it has been shown, pursues its customary course regardless of subsequent injections at intervals of forty-eight hours; beyond a period of six or seven days from the date of the first injection the appearances of the lung have been practically normal, and have remained normal even when the injection has been seven times repeated. It would seem, therefore, that the proliferating cells arising from the first injection become refractory to subsequent injections of the same solution.

Professor Passey records the completion of the experiments with sudan III, referred to in last year's report; it was then observed that the injection of sudan III into the rabbit produced a graded series of lesions in the liver, conforming more or less strictly to acute yellow atrophy, cirrhosis, and multiple nodular hyperplasia in the human subject. There are now reported twelve examples of multilobular cirrhosis and multiple nodular hyperplasia of the liver, but no case of primary liver cell cancer. As a rule, the epithelial proliferation of the lung following the intrapleural injection of sudan III and bile salts has regressed within three to six months, thus pointing a striking contrast in the effects produced by the fat-soluble sudan III and bile salts on the one hand, and by the solutions of electrolytes on the other. The two reagents, a lipoid-alterant and a colloid-alterant, which might be expected to exercise selective effects upon the cell-lipoids and the cell-proteins respectively, can initiate epithelial hyperplasia with equal facility; but the reaction produced by the lipoid-alterant is sustained for a period of months in the presence of an excess of the reagent, whereas one injection of the colloid-alterant inhibits the action of a second injection given forty-eight hours later. These results may provide a basis for the study of the conditions which favour the maintenance of aberrant epithelial hyperplasia in the mammal, a problem which, in some respects at least, is distinct from that concerning the initiation of the hyperplasia.

Dr. G. H. Shaw, working in the department, has shown that another surface-active organic compound—namely, saponin, in a dilution of 1 in 2,000 in physiological saline—can produce hyperplasia conforming to that produced by bile salts, and has conducted experiments designed to submit Loeb's valency rule to a more critical biological test. On theoretical grounds it seemed that if proteins of the living cell membrane could be made electro-positive by the exhibition of suitable "buffer" solutions, then the anion of a neutral salt might be enabled to exercise its specific depressing effects on the physical properties of the proteins, culminating, perhaps, in cellular proliferation. Dr. Shaw's preliminary experiments have shown that, while cells can survive relatively wide variations in the hydrogen-ion concentration of their environment, their susceptibility to neutral solutions—sodium chloride, for example—is profoundly altered; thus a relatively weak solution of common salt, which exhibited in distilled water produces no gross reaction, becomes highly effective in the production of hyperplasia when it is added to an acid "buffer" solution, which is of itself ineffective. Work is now in progress designed to elucidate the nature of this interesting phenomenon.

Inhibition of Tumour Induction.

Dr. I. Berenblum,[1] in investigating the relation between the vascular response brought about by carcinogenic agents and the resulting tumour formation, attempted to modify the blood supply of an area subjected to repeated tarring by the application of two agents known to effect marked local hyperaemia—namely, carbon dioxide snow and mustard gas. Contrary to expectations, he found that in certain conditions repeated mild freezing with carbon dioxide snow is capable of inducing malignant tumours. To the laboratory worker this result is interesting as an example of cancer induction by a physical agency; to the clinician it is important on account of the frequent use of this agent in therapeutics. The fact that there is no record of cancer following the therapeutic use of carbon dioxide snow is understandable when it is realized that to induce cancer not only must treatment be carried out with very carefully balanced doses over a period representing a third of the lifetime of a mouse, but that even under these exacting conditions only three malignant tumours were obtained in seventy animals subjected to the experiment. No case of cancer arising from the frequent application of mustard gas was observed, an indication that irritation by itself will not necessarily result in cancer. Combining the application of tar

[1] Tumour-Formation Following Freezing with Carbon Dioxide Snow. *British Journal of Experimental Pathology*, 1928, vol. x, p. 179.

with carbon dioxide snow in one series of experiments and with mustard gas in another produced unexpected results. In the former series no augmentation of the cancer-producing properties of the tar was obtained; indeed, in the area where the applications of carbon dioxide snow and tar overlapped no tumours developed at all. In the latter series it was found that the presence of mustard gas, far from enhancing the carcinogenic action of the tar, was accompanied by an almost complete inhibition of tumour formation. This effect is not due to any neutralizing action, as the same result is obtainable if the mustard gas is applied separately in the intervals between tarring. Moreover, if a series of mice which have been subjected to tarring up to a point when the first warts are due to appear are then treated with the same tar to which mustard gas in acetone has been added, the subsequent appearance of tumours is almost completely inhibited, although the tarring be continued. It would seem that the processes which almost inevitably terminate in cancer can be interrupted at any stage, provided a tumour has not already appeared. Once this has occurred the same means seem powerless to check its progress.

Melanosis.

Experimental work and study of naturally occurring animal and human melanomata have shown that in these tumours certain of the most heavily pigmented cells are not malignant, but phagocytic, in nature. This finding is of considerable clinical importance, as the presence of pigment-bearing phagocytes in the lymphatic glands draining the site of a melanotic tumour may, without such knowledge, lead to the diagnosis of secondary deposits and an adverse prognosis in keeping. When the readiness with which pigment is taken up by phagocytic cells is more widely understood light may be thrown on the much-debated question of the nature of the cells from which melanotic tumours originate.

Cancer of the Lung.

Attempts to induce malignant disease of the respiratory tract in mice by exposing the animals for a short time daily to a high concentration of tobacco smoke over a period of some sixteen months have failed completely. Deaths from carbon monoxide poisoning were frequent, but otherwise the mice showed no ill effects attributable to the smoke; in fact, they appeared exceptionally healthy. At necropsy the lungs showed no characteristic lesions. It is pointed out in the report that from this failure to produce lung cancer it must not necessarily be concluded that tobacco smoke plays no part in the production of these tumours in man; the choice of experimental animal, the dose, the period of exposure, and many other factors may have been at fault.

THE NATIONAL CAMPAIGN AGAINST RHEUMATISM.

A FURTHER stage in the national campaign against rheumatism was reached at a meeting held at the House of the Royal Society of Medicine on June 26th, with Sir THOMAS HORDER, Bt., M.D., in the chair.

It will be recalled that in November last, at a conference of those interested (*British Medical Journal*, November 17th, 1928, p. 908), an executive committee was appointed to draw up a constitution for a body which it was decided should be called "The National Association for Combating Rheumatism." The proposed constitution and policy as framed by that committee was read to the recent meeting by Dr. MATTHEW B. RAY, who has acted as honorary secretary. It has been decided that the council which is to have the general direction and management of the campaign shall consist of persons elected at a meeting of supporters, also of those holding honorary office or membership of the committees, together with co-opted members—namely, persons whose membership would, in the opinion of the council, advance the interests of the campaign, and persons also who are nominated from time to time by any institution or body invited to do so by the council. The first chairman, vice-chairman, and honorary secretaries will be appointed by the council at its first meeting. It is proposed to have a medical committee and an industrial committee, the latter to include representatives of the Ministry of Health, municipalities, and industrial organizations.

In a statement of policy the objects of the campaign were summarized under five headings. The first was education of medical and public opinion, of patients and their friends, and of employers of labour. The second was the support and co-ordination of research into the causes of these diseases. The third, the increase of facilities for the treatment of rheumatic disease. This would be brought about by the formation of an arthritis unit or special hospital department, working in close co-operation with the medical school, fulfilling also the purposes of research, clinical investigation, and preliminary treatment; the development of existing facilities at general hospitals; the formation of centres for physical treatment in liaison with research laboratories; spa treatment; and the co-ordination of arrangements for following up discharged patients. The fourth heading was the establishment of uniform standards of classification and record, and the fifth the collection, translation, and distribution of information relating to the rheumatic diseases.

There was a need for educating medical opinion as to early diagnosis and the necessity for prompt and continuous treatment. Not only should prevention be in the forefront; there should exist an organized mechanism for following up cases, and advising or securing efficient home treatment, and giving suggestions as to suitability of occupation. Employers of labour, it was felt, ought to be invited to co-operate in this work.

Research concerning these diseases must include co-operation between laboratory worker and clinician, and between the latter and the biochemist, the radiologist, and the social worker, while climatic and other factors must also be studied. Centres should be formed for this special treatment, and these should be in working liaison with the laboratories. Uniform recording of results of treatment should also be aimed at; it would greatly aid statistical compilation and enable the results of particular treatments to be properly assessed.

Sir CLAUDE HILL (Governor of the Isle of Man), in moving the adoption by the association of the proposed constitution, mentioned that he was a member of the Council of the British Red Cross Society, whose activities included those of dealing with rheumatic diseases, though the field intended to be covered by this new body was much wider and more thorough. He was greatly impressed by the narration of the constitution and policy set out at this meeting. He hoped industrial interests would rally efficiently to the aid of this campaign. He thought the organizing secretary of the new body would be a man who could travel a good deal, so that he could familiarize the leaders of industry in various localities with the needs of the work. Dr. MALCOLM CAMPBELL (Droitwich) seconded the motion, and emphasized the amount of active co-operation which women's societies could give. The resolution was carried without dissent.

The CHAIRMAN intimated that the Prime Minister had accepted the invitation to be a member of the council of the association.

Dr. E. I. SPRIGGS said that in discussing this campaign with other people and trying to enlist their aid he had found it helpful to insist that this was not a charitable appeal. Though rheumatism affected certain classes more than others, it occurred throughout all grades and in all parts of the country. Also it should be clearly understood that it was not wished that this organization should replace or absorb any other body; its aim would rather be to act in accord with them in the prevention and treatment of rheumatism, and it was "bad business" to have that carried out in different places separately.

Dr. FORTESCUE FOX also emphasized the importance of the organization keeping in touch with all who were interested in this work; and this applied not only to our own country, but also to those active in the same direction in other countries. It was of the first importance that knowledge on the subject derived from various sources and in different countries should be pooled, with the one great object in view.

Dr. VAN BREEMAN (Amsterdam) spoke as the secretary of the International Society on Rheumatism, and drew attention to the projected international conference on the subject, to be held at Budapest in October next. The points for study included the relation of chronic to acute rheumatism, the medico-scientific, hygienic, and statistical aspects, and the significance of serological and blood examinations in rheumatic diseases.

The names of 74 supporters of the movement were read out, and the council will be formed from those accepting the invitation to serve.

EPSOM COLLEGE.

ANNUAL GENERAL MEETING.

THE annual general meeting of Epsom College was held at the office, 49, Bedford Square, W.C., on June 28th, under the presidency of Dr. RAYMOND CRAWFURD, chairman of the council.

The scrutineers reported that the following candidates were successful at the election of pensioners and foundation scholars.

	Votes.
Pensioners:	
*Mylan, Dr. James G.	6,723
*Johnstone, Dr. George W.	5,936
*Ogilvy-Ramsay, Mrs. Isabella	5,673
‡Alford, Mrs. Mary A.	5,417
†Benson, Dr. Alfred	4,897
‡Harris, Dr. Arthur G. R.	4,584
Foundation Scholars:	
Porter, John D.	21,027
Hogg, Robert D.	13,926

* Ordinary pensions. † Highett pensioner.
‡ Burney Yeo pensioners.

The annual report referred to a gratifying increase in the amount received from annual subscriptions and to the generous support given by the Medical Insurance Agency, the Charities Committee of the British Medical Association, and numerous Panel Committees. The report called attention to the deficit of about £2,000 in the War Memorial Fund, which was instituted by the Old Epsomian Club in order that the nave of the College chapel might be rebuilt in harmony with the new chancel. With regard to the new sanatorium fund, the council, while acknowledging many welcome donations, including £200 from St. Bartholomew's Hospital Medical College, regret that the total sum is not increasing more quickly, and urge that further donations should be procured. It was estimated that the building and equipment would cost £30,000. One advantage which would accrue by the erection of the new sanatorium would be that the old building could be adapted for the admission of about forty more boarders from among the applicants who had to be declined each year. The benefactions received by the College included £500 from the Medical Insurance Agency, to form a nucleus of a fund to establish in perpetuity the Dawson Williams Presentation Scholarship of £150 a year, in memory of Sir Dawson Williams, Editor of the *British Medical Journal* 1893 to 1928. The sum of £1,000 had also been received from Mr. Stanley Baldwin out of the sum placed at his disposal by Lord Beaverbrook in gratitude for his escape in a motor accident. The sum had been earmarked for the furtherance of scientific education at the College. A bequest of £997 had also been received under the will of the late Dr. Alfred Mason, a former scholar of the school. The health of the school during the year had been exceptionally good.

Dr. Raymond Crawfurd, in moving the adoption of the annual report, stated that if two sums of £5,000 were forthcoming the work of the new sanatorium could be put in hand at once. He called attention to the fact that during the year the council had brought into force a much improved scale of salaries and emoluments for the assistant masters, which had been greatly appreciated. The College had to deplore the loss by death of Lord Rosebery, president, Dr. de Havilland Hall, vice-president, and for some time vice-chairman of the council, and Mr. A. Mackay, a member of the council.

England and Wales.

Address by Lord Dawson at the London Hospital.

THE annual distribution of prizes at the London Hospital took place on June 28th. Following the report of the dean (Professor William Wright), which laid emphasis on honours gained by "London" men during the year, Lord Dawson of Penn handed the prizes to the recipients, and addressed the distinguished gathering. After paying a tribute to the late Lord Rosebery, who some years ago delivered a noteworthy speech at the hospital on a similar occasion, Lord Dawson went on to say: "Surpassing me as my predecessors have done in most of their qualities, I have one unique advantage over them all, and that is that I am one of yourselves. I have trodden the same paths, made the same mistakes, carried through the same adventures, and offered the same excuses. I have also known what it is, in my student days, to be relatively prosperous one week and hard up the next. What a glorious time it was! Humanism and humour, and with it all an abounding vitality. The function of youth is to be young in fact, and it is equally the function of age to be young in spirit." Referring to a remark in the dean's report regarding the honours which had come to Lord Dawson himself and to other "London" men, Lord Dawson said that any man who received such distinction must feel a new sense of gratitude to his old school. Any distinction of the kind was to be prized because primarily it brought honour to the profession and offered a wider opportunity for usefulness. It delighted him to think that two members of the team of workers in connexion with the King's illness—and although the workers showed variety in their thinking, which was what a team was for, they were one in feeling and devotion—were "London" men. This gave him the opportunity of acknowledging the debt to the nurses. The four nurses in attendance on the King represented as it happened the four parts of the kingdom, but two of them belonged to the London Hospital. They had extended its reputation, which rested in an uncommon degree upon the character of its nurses. In congratulating the prizewinners of the day, Lord Dawson remarked that those who had not received prizes must not be discouraged. It had to be remembered that students did not all mature at the same time; their gifts did not come to fruition by the same stages. The profession which they were entering called for a multiplicity of qualities. Great as was the importance of academic knowledge and training, there were other attributes which were required of the successful man, including judgement, the faculty for decision, courage in taking risks, and the discipline which could disregard the calls of selfishness and sloth. The work of the medical man was such as levied toll upon brain and heart at the same time. Lord Dawson went on to remind the students that whatever discoveries might be made they would always be thrown back upon clinical experience. Disease was not a standardized product. Man preserved his individuality in disease as well as in health, otherwise it would be an uncommonly dull world to live in. With regard to the future of the medical practitioner, he struck a hopeful note. The people who croaked were always those who mistook change for decadence. The teaching of medicine in Britain to-day was very well done, though the world was not always given the opportunity of seeing how well done it was. Research in this country was rich in brains and increasingly rich in opportunity. All schools and universities were fully alive to the importance of the extension of knowledge and the co-ordination of effort. But it was to the field of general practice that most attention must be paid. The general practitioner was the backbone of medicine. It would be a sorry day for this or any other country when general practitioners were weakened in their influence or their work. The general practitioner was a protection against the stunt specialist. It was to the interest of the community to identify the health of the people with the practitioner, and to give him a career. At the same time he urged the necessity of more institutional provision. He reminded the gathering of the changes in administration which would result from the operation of the Local Government Act, and advised the students and newly qualified practitioners before him to take a bold share in the shaping of the health policy of the country. The success of that policy would depend very largely upon

the vigour and intellectual ability which the younger medical men now coming to the fore brought to bear upon it.

The Child Guidance Council's Clinic.

The Child Guidance Council announces that the work of the clinic at Tudor Lodge, Canonbury Place, Islington, will start about the middle of this month, and that patients will be accepted from that date. The clinic, a preliminary account of which appeared in our issue of May 11th (p. 877), owes its origin to generous financial help from the Commonwealth Fund established by Mrs. Stephen V. Harkness in 1918 "for the welfare of man." In the United States a number of demonstration clinics set up by the Fund have, after varying periods, usually three years, been taken over by local authorities. The Child Guidance Council, though officially not connected with any public authority, is fully alive to the importance of associating its work with that of the education authorities, and believes that, to ensure proper training of the staff of child guidance clinics, the movement must be linked with the university education and social science departments. In choosing the premises for the clinic the council favoured a site within easy access of schools, child welfare centres, nursery schools, and a juvenile court. The clinic now established has not only these advantages, but is housed in an attractive building having a pleasant garden, and is near the chief university and medical schools. The staff consists of a director, a psychiatrist, and an assistant psychiatrist; a chief and assistant psychologist, both intimately acquainted with the work and the problems of the schools; specially trained social workers known as mental health workers; and a number of clerical assistants. The Commonwealth Fund has enabled some of this personnel to make observational visits to the United States, and several of the social workers have had a year's special training in New York. The clinic, having received the general approval of the Board of Education, will co-operate closely with the school medical service of the London County Council, and the staff are assured of the help of the officials, teachers, and care committees associated with the administration of educational work. In addition, the clinic will receive children under school age from child welfare centres, children from institutions, homes, organizations, and dispensaries, and, directly or through the probation officer service, from the juvenile courts. As far as practicable, it will be ready to deal, in co-operation with the National Institute of Industrial Psychology, with cases referred for vocational guidance. The clinic will endeavour to do much of its work by means of staff conferences, where the results of the various investigations made by the psychiatrists, the psychologists, and the social workers may be effectively correlated, and a line of treatment prescribed based on all the ascertainable factors in the life of the individual. It hopes that these conferences may be attended by others than the clinic staff who have immediate knowledge of the child—such, for example, as the teacher, the care committee worker, and the probation officer. Those desirous of taking up the social side of child guidance can avail themselves of the special one-year post-graduate course in mental health to be started in the autumn at the London School of Economics; and the council, through the generosity of the Commonwealth Fund, is able to offer six scholarships of £150 each, tenable by students taking this course. Particulars may be had from the Secretary of the Child Guidance Council, 24, Buckingham Palace Road, S.W.1.

Instruction in Radium Therapy.

A post-graduate course on radium treatment and technique will be held at St. Bartholomew's Hospital and College from September 30th to October 3rd inclusive. The course, for which the fee is five guineas, will be introductory in character and the classes limited to about thirty men, preference being given to those who are likely to work with radium. Lectures and demonstrations will be given on the following subjects: the physical properties of radium and radon (Professor Hopwood); types of appliance used in radium therapy and in the preparation of radon emanation; carcinoma of the rectum (Sir Charles Gordon-Watson); perineal and abdominal insertion of radium; treatment of carcinoma of the tongue and mouth (Professor G. E. Gask); uses of radium in gynaecology (Dr. Malcolm Donaldson); biological aspects of radium (Dr. R. G. Canti); new growths of the larynx and air passages (Mr. W. D. Harmer); carcinoma of the breast (Mr. Geoffrey Keynes); surface application of radium (Dr. N. S. Finzi); and the use of radium in combination with deep x rays (Dr. W. M. Levitt). The course will further include demonstrations of cases in the out-patient department; operations conducted by Sir Charles Gordon-Watson, Professor Gask, Dr. J. D. Barris, Dr. Donaldson, Mr. F. A. Rose, Mr. Bedford Russell, and Mr. Keynes; and a demonstration by Dr. Canti of a film showing the growth of malignant cells. In our issue dated June 29th (p. 1188) we announced a similar course which will be held at the Westminster Hospital Medical School from July 29th to August 3rd.

Social Centre for London Flat-dwellers.

An interesting social experiment has been started in connexion with one of the large estates owned by the Metropolitan Housing Corporation in the poorer districts of London—namely, the Albany estate at Camberwell. In the midst of eighteen blocks of working-class flats which the estate comprises, a social centre has been opened, in premises which were formerly a suite of offices. The centre comprises a library for adults and children, a boys' workroom, well equipped with benches and tools, a girls' club room, a nursery, where mothers can leave their children in safe and happy keeping, a kitchen, for cookery lessons and demonstrations to women, and a model flat furnished on hygienic and economical lines, with a view to showing what is possible even in a tenement. Various services are to be conducted from the centre for the benefit of the tenants, including an arrangement for an assured pure milk supply to every flat. A course of lectures by medical men and women and others on health and hygiene has also been arranged. But the chief thing is the installation of a resident matron, a woman with a training in nursing and a long experience in social welfare, who is to be available for consultation by the tenants. It is emphasized that this is not a charitable enterprise, but a business proposition, made possible by co-operation between landlord and tenant, and paid for by the tenants in their weekly rental. Each of the blocks of flats included in the service of the centre elects a representative on the administrative committee. The centre was opened on June 27th by Mrs. Claude M. Leigh, wife of the director of the Metropolitan Housing Corporation, and named, after her mother, the Augusta Johnson Centre. The occasion, which appeared to be a very popular and festive one among the inhabitants of this rather depressing district of South-East London, was attended by the mayors of Camberwell and Southwark, and by several members of the medical profession.

Ireland.

Irish Medical Association.

THE adjourned annual meeting of the Irish Medical Association was held on June 19th in the Royal College of Surgeons, Dublin. Mr. P. E. Hayden, F.R.C.S.I., was elected president, and in the course of his presidential address referred to the outstanding activities of the association during the past year, and the many ways it helped members. He also called the attention of members to the advantages of the insurance bureau. A warm vote of thanks was accorded to the outgoing president, Dr. H. T. Warnock. Votes of sympathy were passed with the relatives of Sir William Thompson, M.D., and Dr. J. J. Kinsella, Edenderry.

Dr. Canti's Film in Dublin.

At a very largely attended meeting of the Leinster Branch of the British Medical Association, held at University College, Dublin, on the evening of June 14th, with Professor M. R. J. Hayes in the chair, Dr. R. G. Canti of St. Bartholomew's Hospital gave a lecture, with cinematographic demonstrations, on living tissue cells

cultivated *in vitro*, including the action of radium on them. The chairman, in calling upon Dr. Canti to deliver his lecture and show his film, said the Leinster Branch felt highly honoured at having Dr. Canti with them that evening, inasmuch as it was the first time that the film was being shown in Ireland; Dublin was, therefore, the first centre visited by him. Continuing, he said that when he first saw this wonderful film in Stockholm he looked forward to an opportunity of seeing it a second time, and hoped to induce Dr. Canti to bring his film to Dublin. Now his wish had been fulfilled, and he anticipated admiring the film more now than he did then. Dr. Canti, before showing the three films, outlined the technique employed by him for the growth of tissues *in vitro*, and threw on the screen some slides showing the apparatus, with its ingenious arrangements by which the films were taken, and which made possible a study of various influences affecting cell proliferation and tissue growth impossible by any of the older methods of growth study. He explained that this method of cellular cinematography made it possible for one to obtain a permanent record of a series of rapidly succeeding events, which could be studied afterwards at leisure, either as individual pictures or in sequence, and that also the pictures could be speeded up, so that a sequence of events which might extend over a prolonged period of time could be hurried through its different stages in quick succession. The pictures he would show were speeded up, some 240, some 480, and others 960 times, this was done principally for convenience, since many of the observations were carried over periods of twenty-four hours. The first reel was of normal chick periosteum and Jensen's rat sarcoma, showing dividing cells under high magnification and movements of chromosomes, together with reformation of nucleus, degeneration, and phagocytosis. The second reel showed the action of beta and gamma rays of radium on these cells. The third reel, dark ground illumination and high magnification, showed the internal structures of the cell and their movements. After the demonstration Dr. D. J. Coffey, president of University College, in proposing a vote of thanks to the lecturer, said that he admired the film for its deep interest and great possibilities, and hoped that they would have an opportunity of seeing similar films of medical interest. Dr. Gillman Moorhead, regius professor of medicine, Trinity College, seconded the vote, which was unanimously accorded to the lecturer. Professor Hayes subsequently entertained Dr. Canti, with the members of the profession, at supper in the Shelbourne Hotel.

Provisions of the Milk and Dairies Bill.

The Milk and Dairies Bill, shortly to be introduced in the Dail, aims at the production of clean milk by enforcing strict supervision of the cow, the dairy, and the methods of milk distribution. To these ends a wider interpretation is given to the terms "milk" and "dairy," and the registration of all dairymen, as well as their premises, is made mandatory. The local authority can refuse registration or remove a name from the register. Since the publication of the report of the Interdepartmental Committee appointed to advise on the measures necessary to secure the cleanliness of the milk supply many public bodies and committees of management of hospitals, sanatoriums, and maternity and child welfare organizations have tried to raise the standard of cleanliness by making the purity of the milk, as shown by bacterial content, the basis of contracts. The regulations under the new law will not only deal with the lighting, ventilation, cleansing, drainage, and water supply of the dairy, but will secure a more thorough supervision and examination of dairy cows, personal cleanliness of milkers and distributors, the cooling of milk, and its conveyance and distribution in sterilized vessels and utensils; the grading of milk and the use of special designations will be authorized, and there will be drastic penalties against purveyors of dirty milk. Effect has already been given to certain administrative measures recommended by the committee. The Public Health (Infectious Disease) Regulations of 1929, which replace the regulations of 1919, provide for the examination of suspected carriers of enteric fever, diphtheria, and dysentery infection employed in connexion with the production or handling of milk, and for the prohibition of their employment in any trade concerned with the preparation or handling of food or drink intended for human consumption. The bill now to be introduced enables a medical officer of health to stop the sale of milk if there is any evidence that it is the vehicle of infection. The safeguards relied on in the bill for the protection of the public against infection with the bovine tubercle bacillus are: (1) inspection and examination; (2) the tuberculin test; and (3) bacteriological examination. It is provided that the milk of cows suffering from any of the following conditions should not be sold for human consumption: tuberculosis of the udder or uterus, acute or chronic mastitis, actinomycosis of the udder, anthrax, foot-and-mouth disease, or any other condition of the cow, udder, or teats likely to convey disease. Furthermore, provision is made for stopping supplies of milk from any outside district to which infection has been traced. The higher grade milk proposed under the bill must be produced from cows which have passed the tuberculin test and a clinical examination; the entire herd must be submitted to the test and to the veterinary examination at intervals of six months, and every animal must have passed the test before its admission to the herd. Power is given to sanitary authorities to establish milk depots for the sale of milk specially prepared for consumption by children under 2 years of age. Other provisions of the bill deal with the control of condensed, dried, and separated milk, with buttermilk, and the vexed question of fixed standards in connexion with the Sale of Food and Drugs Act. In commenting on the new bill, Dr. Edward F. Stephenson, chief medical adviser to the Department of Local Government and Public Health, says that to attain its object the appointment of a medical officer of health to every county is vital. Success can only be achieved by steady, firm, and uniform administration exercised by whole-time trained sanatarians. The value of these officers is now well recognized and the need for their appointment is being pressed.

Meeting of the British Pharmaceutical Society.

The annual meeting of the British Pharmaceutical Society was recently held in the Mansion House, Dublin. There were close on six hundred delegates present. The City Commissioners welcomed the members on behalf of the citizens of Dublin. The President of the Irish Free State, and General Mulcahy, Minister for Local Government and Public Health, were present at a reception given to the members of the Pharmaceutical Society. The Governor-General of the Irish Free State attended the banquet. The Chairman of the British Pharmaceutical Society, Mr. R. R. Bennett, B.Sc., delivered an important address on the changing foundations of materia medica, of which an account was given in this column last week at page 1177.

Scotland.

Treatment of Mental Disorder.

IN his last annual report Dr. W. D. Chambers, physician-superintendent of James Murray's Royal Asylum, Perth, comments on the increase during recent years in the number of patients admitted to this well-known mental institution, now in its 103rd year. In 1925 the number on the registers was 137, in 1927 it was 173, and in the year under review, 192. This rapid growth was for a time embarrassing. Mental cases, Dr. Chambers observes, are commonly urgent, and the hospital would fail in its service to the public if it became unable to receive acute cases as they arose. Fortunately, it was never necessary to refuse admission to any acute patient, but it became apparent that the accommodation was now being taxed nearly to its limit, and that more accommodation, especially of the hospital type for acute and recent cases, must be provided, unless the scope of the institution was to be curtailed. With a turnover of 50 per cent. of the population each year larger provision for acute cases became imperative. Further extensions to the main building being impracticable, even if desirable, the decision has now been made to build a detached and self-contained

reception hospital for 40 beds. An excellent site has been chosen, and it is hoped soon to make a start with building operations. The new block will be completely equipped with facilities for treatment, including a surgery and dental room, a laboratory, an electrical treatment room with *x*-ray apparatus, ultra-violet lamps and other appliances, means for hydrotherapy, and clinical treatment rooms. In this connexion it is interesting to note elsewhere in Dr. Chambers's report that a very considerable amount of therapeutic work is now being done at the Royal Asylum. Septic foci, particularly in the mouth and the urinary system, have been investigated and treated, and a number of urinary antiseptics were exhaustively tried last year on a variety of cases. Where intestinal stasis was recognized or suspected attempts were made to deal with it. A long series of cases were treated by means of protein shock therapy, and another series by ovarian extracts and preparations, either singly or in combination. On the whole the results could not be regarded as more than encouraging, and in some cases they were definitely disappointing. Full use was made of the ultra-violet lamp, but here again the results were confused and uncertain. Occupation therapy in the arts and crafts department was on the whole very successful, and a large proportion of cases have attended for instruction, much of the work being of the highest standard and satisfactory both to teacher and to taught.

Annexe to Glasgow Victoria Infirmary.

What was described as a new development in the work of voluntary hospitals was inaugurated on June 27th, when the auxiliary hospital of the Victoria Infirmary, Glasgow, at Philipshill, near Busby, Lanarkshire, was formally opened by Mr. W. Gilchrist Macbeth of Dunira, Crieff, who was a generous donor towards the scheme. Beautifully situated in the heart of rural scenery and lying 500 feet above sea-level, the grounds of the extension cover 33 acres. The wards are built on the pavilion system with verandahs and sun rooms, and the two pavilions which have been completed each provide accommodation for 50 beds. There will eventually be eight pavilions, in addition to the administrative block, operating theatre, etc. The new hospital is designed for patients who have passed the acute stage of illness and may thus be removed from the central infirmary to make room for urgent cases awaiting admission. The total cost of the scheme is estimated to be £120,000. Dr. Walter Elliot, M.P., the former Under-Secretary of State for Scotland, gave an address at the opening ceremony, and dealt with the provision made in the Local Government Act for safeguarding the voluntary hospitals under the system of unified health service control.

Royal Blind Asylum, Edinburgh.

The directors of the Royal Blind Asylum and School, Craigmillar Park, Edinburgh, have issued their report for the year ended March 31st. The outstanding feature of the year has been the opening of the Thomas Burns Home for Blind Women at West Craigmillar. In the technical department there are now 78 blind persons undergoing training at Gillespie Crescent, and 27 at West Craigmillar. Within the next four years over 40 will complete their training, and the directors will be faced with the problem of finding employment for these industrial trainees. The ordinary subscriptions for the year have amounted to £8,157, which is a record in the history of the institution. The work can only be carried on, however, by considerable drafts on the legacies received. The Scottish National Institution for Blinded Sailors and Soldiers has also had a successful year. The principal activities of this institution are the employment and care of the 120 men who have been trained; 35 of them are employed in the workshop at Newington House, Edinburgh, and 20 in the workshop at No. 2, Queen's Crescent, Glasgow.

Tuberculosis in Fife.

In a recent report by Dr. Pratt Yule, medical officer of health for the county of Fife, it is stated that the death rate from tuberculosis in the county in 1928 was 0.70 per 1,000 of the population, which is less than half that obtaining just before the war. Of the factors responsible for this satisfactory state of affairs, doubtless the most important is the steady campaign that has been waged against the disease since 1912. The Fife scheme differs from that usually accepted as necessary for the control of tuberculosis in that dispensaries have not been established, the patient being visited, examined, and supervised in his home. The incidence and mortality rates compare favourably with those of other Scottish counties of like industrial characteristics.

Correspondence.

THE UNKNOWN FACTOR IN VACCINATION.

SIR,—It goes without saying that decreased resort by the public to anti-small-pox vaccination, with resultant loss of lives and finance, must eventuate following recent repeated reports in the lay press of deaths incident to its practice. The Ministry of Health has issued a report[1] on this subject, showing that an earnest effort to identify the "unknown factor" of evil has been pursued by impartial and exceptionally skilled inquirers. Notwithstanding analyses of all available evidence and a series of well-considered experiments, the *causa causans* still evades recognition. All that has emerged is the framing of certain hypotheses. Obviously this stage should not be regarded as justifying the abandonment of further inquiries or an assumption of the fatalistic attitude of conceiving the "unknown factor" to be not only an undesirable but an inevitable accompaniment of anti-small-pox vaccination. Further investigation is essential in the interest of human life. We would therefore invite special attention to the following extract from the minority report signed by Professor McIntosh:

"... before vaccinia virus can definitely be put out of account as a possible etiological agent, more data will have to be obtained concerning the frequency of these cases and the neurotropic effects of vaccinia about which, at present, there is some difference of opinion."

Pending further investigation, we hold from the evidence given in the body of the report that the vaccinia virus has not been put "definitely" out of account; and we therefore advocate that the present strain of vaccine used in this country (which has largely passed through rabbits to calves) be scrapped and, in its place, either a stock of vaccine be obtained from a country where rabbits have not been utilized, or a new stock of variola vaccine be cultivated without the rodent accessory. This procedure would afford, so far as records of the period anterior to use of rabbits in vaccine cultivation permit of judgement, a method of exclusion both safe and quick.—We are, etc.,

MYER COPLANS,
W. G. KING,
W. J. R. SIMPSON.

Ross Institute and Hospital for Tropical Diseases, Putney Heath, S.W.15, June 28th.

VACCINATION AND ENCEPHALITIS.

SIR,—Reports of recent inquests, leading articles in the newspapers, and your article on post-vaccinal encephalitis (June 29th, p. 1174) will inevitably do much to shake the faith of the general public in vaccination. I have read a number of the reports and articles on this subject, and I suggest that the assumptions made therein are premature to a dangerous degree. I fail to find in the writings any sound scientific argument whatever to substantiate the name "post-vaccinal encephalitis."

One of our elementary rules in the conduct of scientific investigation is not to connect cause with effect except by experimental proof confirmed by clinical observation, and yet here we have committees connecting a particularly unknown type of encephalitis to vaccination and startling the public by a statement to which *their* only possible interpretation is that vaccination *produces* (I use the word advisedly), either directly or indirectly, this dread disease in one out of every 16,900 cases, and that half of those

[1] Report of the Committee on Vaccination. Ministry of Health. Cmd. 3148. 1928.

affected die; a truly ghastly suggestion when each parent thinks that his or her child may be the unfortunate one in 33,000!

During the past eighteen months I have seen two cases of chicken-pox, one of measles, and one of influenza, in all of which the onset occurred within fourteen days of vaccination, and presumably there are thousands of such cases. Is it, then, any less likely that a more serious but more obscure disease may not equally well be liable to begin shortly after vaccination?

Take now the case of this obscure encephalitis in children. We find it occurring in a mere handful of cases after vaccination. Because it is not, we think, one of the well-known types of encephalitis, and because *the cases brought to general notice* are post-vaccinal, we at once dig about trying to *connect* it with vaccination. Surely the better thing to do is to try and find out how many cases of sin[illegible] apart altogether from the factor of [illegible] that there are probably hundreds of such cases, and that, if they were discovered and as extensive pathological studies made of them as have been made of the post-vaccinal cases, quite probably the incidence of the condition, apart from vaccination, would be the same age for age as during the few weeks following vaccination. It may be argued that we have no positive information that the disease exists apart from vaccination; but, what is much more important, we certainly have no negative information that such a condition does not exist. I can, in fact, myself recall two cases seen during the past two years which compared closely with the descriptions of these post-vaccinal cases, and both of which recovered.

The solution to the problem of how best to deal with these obscure conditions in order to gain information about them is exceptionally difficult, and is not my object in writing this letter; but that such do exist in large numbers is, I think, a certainty, the recoveries passing unnoticed and the fatal cases being named according to the known disease which they most closely resemble.

If this scare of post-vaccinal disease does something to stir medical interest in the more obscure types of disease and bring forward suggestions as to how inquiry can be conducted in such cases, it will considerably mitigate the damage already done to the scientifically sound procedure of vaccination.—I am, etc.,

Halifax, July 1st. R. M. PEARCE.

DISPLACEMENT OF THE INTERNAL EPICONDYLE.

SIR,—In his interesting note under the heading "A Comparatively Rare Displacement of the Internal Epicondyle," published in your issue of June 22nd (p. 1113), Mr. Stanley Brentnall states that I make "the manipulative reduction responsible for the displacement of the epicondyle."

Mr. Brentnall has misunderstood me. The brief reference I made to this subject in the course of an address, to which Mr. Brentnall refers in his note, contains the following words: "During reduction by the doctor, by some chance, the separated internal epicondyle was caught between the humerus and ulna." The displacement of the epicondyle is surely the result of the force which produced the dislocation. The catching of the epicondyle between the bones is presumably a matter of chance, since it does not invariably occur. I think we may take it that in the vast majority of cases dislocations of the elbow are produced by force applied in the direction of hyperextension or of abduction, or of a combination of these. In any case the inner side of the joint suffers damage: either the internal lateral ligament is ruptured or the epicondyle avulsed. In the latter case the separated epicondyle remains attached to the ulna, and is forced by atmospheric pressure into the sigmoid notch. When reduction is effected the epicondyle may slip out of the way or may remain in the notch, where it is caught or held by the humerus.

When a pure abduction strain occurs and the damage stops short of complete dislocation as, I think quite rightly, suggested by Mr. Brentnall in his cases, the conditions would seem to be precisely the same: the catching of the displaced epicondyle is a matter of chance. Mr. Brentnall regrets that the direction of the dislocation was not noted in the very brief reference I made to four cases. Since then I have had a further five, making nine in all. One of these was of the type described by Mr. Brentnall: in this there was a definite history that no dislocation had occurred. As to the other eight, in three the dislocation was said to be backwards and outwards, in three backwards, while in two the direction was unknown.

In two cases the ulnar nerve was partially paralysed, but recovered completely after operation. In both cases, operated upon two and two and a half months respectively after the original injury, it was deemed advisable to displace the nerve to the front of the epicondyle.—I am, etc.,

London, W., July 1st. H. A. T. FAIRBANK.

PRURITUS ANI.

SIR,—In connexion with Dr. Ernest Ward's letter in the *Journal* of June 29th (p. 1183) I should like to be permitted to call attention to a type of pruritus ani which in my experience is quite common—that is, pruritus ani of mycotic origin.

This type of pruritus ani was described by me several years ago in the *Journal* (December 1st, 1923) in a paper entitled "Medical mycology," and I gave a full account of it in the *Practitioner* (December, 1926), and in the German Lectures on "Fungi and fungous diseases" delivered before the University of Illinois in 1926, which were published in book form by the American Medical Association last year.

The condition is due to the presence of fungi of the genus Epidermophyton and Trichophyton, the same fungi which produce tinea cruris and pruritus interdigitalis pedum: often *Epidermophyton cruris* Cast. (1905) *Ep. inguinalis* Sabour. 1907) and *Epidermophyton rubrum* Cast. 1909. Yeast-like fungi of the type Cryptococcus, Monilia, Saccharomyces, Schizosaccharomyces are also often present, but their role in the production of the pruritus is somewhat doubtful.

Clinically there may be very few objective symptoms. The patient complains of severe pruritus, not, as a rule, continuously, but at intervals. The pruritus is often worse at night, but the attacks of unbearable itching may come at any time. Inspection of the anoperianal region in some cases may reveal nothing at all except perhaps signs of scratching, but in most cases, on careful examination, minute red, slightly raised, infiltrated patches may be seen in the perianal region, occasionally arranged into two curved lines, or a dry or moist dermatitis may be present around the anus. In some old-standing cases the skin is thickened and lichenified. When the secondary bacterial infection becomes abundant, especially if many coli and proteus germs are present, the fungus may disappear completely or become extremely scarce.

With regard to treatment, tar-salicylic acid ointments or a benzoic acid-salicylic salve (Whitfield's ointment) answer fairly well. In obstinate cases x-ray treatment is advisable; it is often successful, though, unfortunately, not always.—I am, etc.,

London W.1, July 2nd. ALDO CASTELLANI.

SPA TREATMENT.

SIR,—A name may have unlooked-for effects, especially when it becomes a more or less exclusive label for a society or group of medical men. I agree with Dr. Collis Hallowes (June 29th, p. 1181) that in this case at all events "contentious definitions" are detrimental to progress. For practical purposes it is better, if possible, to find a name that will unite in one group all who study different parts of the same subject.

What are the different parts of spa treatment: (1) the internal use of waters; (2) their external use in a variety of forms, with, of course, *accessory* treatments, such as are everywhere employed. As regards (1) I am prepared to admit that the distinction between "ordinary" water and "medicinal" water, like the distinction between vegetables as food and as drugs, although of very great practical importance, is not fundamental.

We have in England no satisfying name for the internal use of waters—the crenotherapy of the Latin races.

Hydrotherapy has been suggested, but since this word was appropriated seventy or eighty years ago for the external use of water in bath establishments it has lost its wider meaning and could no longer be applied to the spa. Words that have decayed or taken on special meanings are generally misleading.

Medical hydrology is the science of hydrological or "spa" treatment. It has two branches, which are, in plain English, *water treatment* and *bath treatment*. The spas provide both. Torquay, Matlock, the new clinics, cannot supply waters, but they can or will supply baths. It is greatly to be desired that these two procedures, which every year sees more firmly established, should, wherever they are practised in our country, take their true alignment under simple general labels not too misleading or contentious.

As regards the "rheumatic diseases," the stimulation of the skin by baths is, in my opinion, an essential part of preventive and curative treatments. How essential time will show, when this stimulation is given, measured, and recorded with the same accuracy as in the use of drugs. The spa, the marine resort, and the clinic must, naturally, as I stated in your columns last August,[1] develop along special lines. All of them have, however, an important service to render in the treatment of industrial rheumatism. To make the scientific use of baths available for insured persons throughout the country will require the co-operation and good will of all medical men who have knowledge and experience in their use. I am sure that Dr. Hallowes, like myself, although we are neither of us now spa practitioners, would like to do his bit.—I am, etc.,

London, July 1st. R. FORTESCUE FOX.

SIR,—As I was associated for many years with the late Professor Albert Robin in his teaching, in which clinical hydrology had an important place, may I add my remarks to those of your other correspondents regarding the interesting and stimulating lecture by Dr. Wilfrid Edgecombe, printed in your issue of June 1st (p. 981)?

The opinion expressed by Dr. Edgecombe can be applied only to the spas possessing indifferent—that is, not potent—mineral waters; spas which are not very interesting from a clinical point of view. Spas with real active mineral waters must be considered as very powerful therapeutic agents, having special indications, and counter-indications, studied by various clinicians, and I refer, amongst others, to the work of Sir Herman Weber in this country, and to that of Professor Robin in France.

To take the example given by Dr. Edgecombe, one cannot send indifferently a patient to Vittel or Aix, because these two stations have each one of them their relative specific action, and patients who are suitable for Vittel, if sent to Aix, will, I think, derive no benefit at all, or may find their condition much worse after their "cure." There is much scope for a specialist internist in the careful study of the indications and counter-indications of the various spas.

I cannot, I think, subscribe to the opinion that "physicians at spas must act as general physicians, making use generally of physical methods, in addition to ordinary therapeutical treatment, rather than purely as spa physicians." I think that spa physicians must stick to the application of their special mineral water treatment. Neither the specialist nor the general practitioner will send patients to the spa simply to have their treatment undertaken by another physician; but both will send them, as they would send other cases to a surgeon or radiologist, for a special treatment, which has its place in the general medical treatment of which they have the exclusive direction. The spa physician is a collaborator of the internist in the same manner as the surgeon or the radiologist may be.

Although I run the risk of being considered as "more Royalist than the King," I think that many British spas are very powerful specific therapeutical agents, and I think that Dr. Edgecombe renders a great service to clinical therapeutics by stimulating with his paper the study of these spas.—I am, etc.,

London, W.1, July 1st. A. P. CAWADIAS.

[1] *British Medical Journal*, 1928, vol. ii, p. 322.

THE DEFINITION OF RHEUMATOID ARTHRITIS.

SIR,—There is much to be said for the proposal made by Dr. Matthew Ray in his letter on this subject (June 15th, p. 1098)—namely, that the term should be limited to the condition in question associated with joint changes, which affects women of the reproductive age. As Dr. A. H. Douthwaite points out, however, in the following number, and as indeed Dr. Ray concedes himself, it is not entirely limited to women. Out of thirty-five cases seen recently five were men.

In view, too, of the confusion in which the nomenclature of chronic arthritis finds itself, some hesitation may well be felt in departing thus early from the classification adopted by the Ministry of Health (Report on Chronic Arthritis, 1928).

Whether Dr. Ray's proposal be adopted or not, he has in making it drawn attention once more, and in a very significant way, to the fact that there is much more in chronic arthritis than the joint changes; there is a whole patient with a background, and there are present signs of a general disturbance.

The sex incidence of rheumatoid arthritis of the atrophic type is most striking, but an even more accurate generalization may be made—namely, that the people who suffer from it are always of the slender body type, the "carnivorous" type of Goldthwait. Why is this so? And why is the female sex so very much more liable than the male? The key to the etiology of the condition may well be found in studying clinical features like these, in large groups of cases.—I am, etc.,

London, June 25th. A. R. NELIGAN.

ELIMINATION OF VENEREAL DISEASE.

SIR,—Technical journals abound with interesting references to the cancer problem. I know of nothing more attractive than an onlooker's view of the attempts which are being made to reach a solution, especially as I am a member of the Cancer Research Committee of the University of Melbourne, and have done my best to help.

The test of the value of all research must in the last resort be the service rendered to mankind. All the statistical investigation indicates the probability, amounting almost to certainty, that the damage done by venereal diseases is greater than that produced by cancer and tubercle. Yet the venereal diseases are for the most part remediable, if sufficient trouble be taken. They are certainly preventable, and they could, by common national action, be removed from the globe. Such a victory, as someone pointed out, would be greater than that of Charles Martel; yet I find eminent biologists and distinguished medical practitioners referring to the necessary practical action as something rather beneath consideration. Enthusiasm for the extirpation of the venereal diseases is certainly not easily produced.

I admit that such a task is not nearly as interesting as the solution of the cancer problem, but is that quite the right way to view the matter? Are we playing a kind of intellectual golf with a possibility or probability of valuable results, or are we in honour bound to render a necessary and certain service to mankind? I see no reason why both procedures should not take place concurrently, but the neglect of the simple problem is not creditable to science. Are we still in the toils of a modified mediaeval mode of thought or are we prepared to face the issue, to shoulder the burden and, unpleasant as the task may be, clean up civilization so far as venereal disease is concerned? Many people seem to forget that we are primarily animals, but in our social adjustments it does not do to forget the fact. A military medical officer who has to deal with thousands of vigorous men, particularly in Eastern countries, is under no illusion respecting the complexity and difficulty of the task, although he realizes its immense importance and also its practicability.

After all, the unit of society is the family, and nothing hits the family more heavily than the neglect to control venereal disease. The solution, however, is a matter for science and not for politics.—I am, etc.,

Melbourne, May 14th. JAMES W. BARRETT.

MEDICAL ATTENDANCE ON PATIENTS IN PRIVATE WARDS.

SIR,—In reference to Dr. R. H. Dix's letter in the *British Medical Journal* of June 29th (p. 1181) with regard to medical attendance on private patients in private wards of hospitals, I should like to go a little further than he does. The restriction that he mentions is not essential.

In the case of the Hampstead General Hospital the *resident* medical staff have no duties in connexion with the private wards. A local practitioner who sends a case into one of these wards retains the case under his own care, and undertakes full responsibility for the treatment as if the patient were in a nursing home. Further, with regard to the honorary medical staff, it is open to the practitioner "to call into consultation any surgeon, physician, or specialist whom he desires, whether on the staff of the Hampstead General Hospital or not. . . . The sole proviso with regard to surgical operations is that they shall only be performed by members of the staff of some recognized general or special hospital in London."

I quote the above passages from a letter recently sent out by the hospital to local practitioners to explain the exact position. The British Medical Association should certainly do nothing to restrict the *full* freedom of choice of consultant, especially where, as in Hampstead, this freedom already exists.—I am, etc.,

London, N.W.3, June 28th. HENRY SHARMAN, M.D.

THE RELATION BETWEEN MUNICIPAL AND VOLUNTARY HOSPITALS.

SIR,—I think it is important that we, as medical men, should realize the difference between even the largest Poor Law hospital and the voluntary hospitals. The Poor Law hospital may be quite up to date in equipment and be staffed by highly efficient resident medical officers, but the system of treatment is quite different from that of a voluntary hospital. At a voluntary hospital every patient (with the exception of casualty cases) is under the care of a member of the visiting staff, and in our great cities this means under the care of a specialist, who, of course, receives the assistance of resident medical officers. In the Poor Law hospitals the patients are under the care of a chief resident medical officer and his staff. There may be consultants attached to the hospital, but the patients are not admitted under them, and they are only called in by the resident medical officer if he thinks it advisable to obtain their services.

If the transferred Poor Law hospitals are to be brought up to the standard of the voluntary hospitals, the relationship of the patients to a staff of specialists must be the same as in the voluntary hospitals. What would this necessitate? If the city councils appoint specialists to the staffs of the transferred hospitals they will either have to pay them a salary adequate for a whole-time service—and this would be an enormous expense to the ratepayers—or the members of the staff must be able to support themselves by private practice. But in any city having already a large number of specialists on the staffs of the voluntary hospitals, the latter course would be impracticable; they would find competition too great. On the other hand, the specialists already on the staffs of the voluntary hospitals could not also hold similar positions in the transferred hospitals; they would have no time for this additional work.

The 600 beds at the large Poor Law hospital with which I was connected, as a member of the management committee, were always in demand, and they will continue to be so when the hospital is transferred to the city council. All the cases, at the present time, admitted to a Poor Law hospital must be admitted to some hospital. It therefore seems to me that the more serious and acute cases, and those which present special difficulty in diagnosis or treatment, should be admitted to the voluntary hospitals under the care of the specialists; and what we may, from a medical point of view, call the less important cases, and those which would occupy a bed too long in one of the voluntary hospitals, should continue to be admitted to the transferred hospitals. The transferred hospitals should, in fact, continue to have the same relationship to the voluntary hospitals as they have at present. In this way no change in the staffing of the transferred hospitals would be necessary, though every possible form of co-operation between them and the voluntary hospitals will be desirable. I would suggest that a joint committee, representing the local authority and the voluntary hospitals, should be set up to arrange for the suitable allotment of patients between the municipal and voluntary hospitals, and to consider any other matters in which co-operation seems desirable.

It is a mistake to suppose that because the Poor Law hospitals are to be transferred to city and county councils the scope of their work should necessarily be altered. They will be free from the stigma of the Poor Law, which, though really unreasonable, discredits them in the eyes of the poor. But the need for hospitals where the class of cases now admitted into Poor Law hospitals can still be received will be just as great as at present. I would suggest that all cases requiring major operations should be admitted, or transferred from the municipal hospital, to the voluntary hospitals for treatment by the surgical specialists, though to deal with major emergency operations the municipal hospitals should appoint surgeons, if they are not already appointed, on their consulting staffs.—I am, etc.,

Bristol, June 23rd. CHARLES A. MORTON.

STELLWAG'S SIGN.

SIR,—What is Stellwag's sign? Tempted by Osler's advice ("Let the old men read new books; you read the journals and the old books") to listen to Stellwag himself as he describes the sign which bears his name, I find myself for my sins unable to consult his original paper in this country. However, Professor Max Neuburger of the University of Vienna has very kindly abstracted for me the main points from Stellwag's article, "Über gewisse Innervationsstörungen bei der Basedow'schen Krankheit," which appeared in the *Zeitschrift der k. k. Gesellschaft der Ärzte in Wien*, 25 Jhg., 1869, 25–54. The following is a translation of the abstract:

"Stellwag explains the widening of the palpebral fissure, *not mechanically, but due to weakening of the nervous reflexes.*

"Such explanation gains in value if one considers the second eye-sign, the infrequent and incomplete blinking. This again is due solely to a diminution and temporary cessation of a reflex, undoubtedly evoked in the sphincter muscle of the eyelids by the retina and the sensory nerves of the eyeball surface."

There are those who will be reminded in this eponymic quest of the familiar tale of the wife of Jeroboam. It would interest them to know who first in the medical literature linked Stellwag's name with the above two phenomena.—I am, etc.,

London, W., June 27th. WALTER R. BETT.

THYROID AND MANGANESE TREATMENT.

SIR,—Dr. Herbert W. Nott reported in the *British Medical Journal* some results of his in an article entitled "The thyroid and manganese treatment in various diseases" (March 7th, 1925, p. 443). Further reports followed in the *Journal* of December 26th, 1925 (p. 1209), and July 17th, 1926 (p. 109). I am anxious to hear what has happened since then. I should like to know what further light has accumulated on Dr. Nott's results, and what the general verdict is up to date.—I am, etc.,

ARCH. LANGWILL, M.D., F.R.C.S.Ed.

Kensington, W., June 27th.

THE THANK-OFFERING FUND.

SIR,—When it was first announced from Buckingham Palace that there would be a National Thanksgiving Day for the King's Recovery, now fixed for Sunday, July 7th, it was suggested that thank-offerings from the congregations might be appropriately devoted to hospitals. It is probable that in London some congregations would like their offerings to go to King Edward's Hospital Fund for London for the benefit of the hospitals of London generally, while others might wish to give them to some particular hospital.

Contributions of both kinds may be sent to the Thank-offering Fund organized by King Edward's Hospital Fund for London at 103, Kingsway, W.C.2. Those earmarked for particular hospitals will be passed on to those hospitals. Those not earmarked will be passed to the King's Fund. The total of the two taken together will then represent the whole of the Thanksgiving Day offerings. It has accordingly been decided that from now onwards the opportunity of earmarking, which was previously extended to those interested in hospitals outside London, is also extended to those specially interested in particular London hospitals. Those who have been waiting till the approach of Thanksgiving Day, but wish to make their contributions through channels other than the church collections on that day, may send direct to the Thank-offering Fund.—I am, etc.,

DONOUGHMORE,
Treasurer.

London, W.C.2, June 27th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The King's Speech.

ON July 2nd the Lord Chancellor, Lord Sankey, read the King's Speech in the House of Lords. Both Houses subsequently discussed it on the Addresses, and the debate in the House of Commons will be continued next week. The Speech does not mention public health, but cognate subjects are raised in the following passages: "Bills will be laid before you for amending and consolidating the existing factory legislation, and for giving effect to the obligations entered into in Washington in 1919. My Ministers propose to introduce legislation to promote an extensive policy of slum clearance and to make further provision for housing in urban and rural areas. My Ministers have decided that the time has come to investigate the whole field of legislation relating to the sale and supply of intoxicating liquor, and on their recommendation I propose to appoint at an early date Commissioners for this purpose."

An examination is promised by the Speech into the working of the electoral law. Ministerialists understand that the subjects to be considered during this inquiry will include the abolition of the university franchise and university constituencies.

Dr. Drummond Shiels, secretary of the Parliamentary Medical Committee in the last Parliament, who is now a member of the Government, has called a meeting of medical Peers and M.P.'s for July 9th at the House of Commons to discuss the setting up again of a medical committee and the choice of its officers.

Medico-Legal.

ALLEGED ILLEGAL OPERATION: ACQUITTAL.

REX *v.* H. WINDSOR BELL.

AT the Central Criminal Court, on July 2nd, before Mr. Justice Swift, Dr. Hugh Windsor Bell of Oakley Street, Chelsea, was charged on an indictment of manslaughter arising out of an alleged illegal operation on Kathleen Alexandra Kelly. The proceedings at the first trial, before Mr. Justice McCardie, when the jury disagreed, were reported at some length in the *Journal* of June 8th (p. 1061). At the second trial the jury recorded a verdict of "Not guilty" without leaving the box, and the defendant was accordingly discharged.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on June 27th the following medical degrees were conferred:

D.M.—W. Dalrymple-Champneys.
B.M.—A. J. M. Melly, Florence H. Johnson.

UNIVERSITY OF BIRMINGHAM.

AT a congregation held on June 29th the following medical degrees were conferred:

M.D.—C. G. Payton, W. D. Beck.
M.B. . . . . .

K. S. Thom, Doris I. Wall.

* With first-class honours. † With second-class honours.

The following scholarships and prizes have been awarded: *Queen's Scholarships*: (second year), P. J. Stoy; (third year), H. N. Gregg; (fourth year), W. E. Wimberger; (final year), W. C. Smallwood. *Ingleby Scholarship*: (final year), W. C. Smallwood. *Arthur Foxwell Memorial Medal*: (final year), W. C. Smallwood. *Sampson Gamgee Memorial Medal for Surgery*: (final year), C. St. Johnston. *Russell Memorial Prize*: E. G. Abdel-Malek. *Peter Thompson Prize in Anatomy*: (second year), P. J. Stoy. *Foyle Prize*: P. J. Stoy.

The following appointments are announced: Chair of Pharmacology and Therapeutics, Dr. K. Douglas Wilkinson; Lecturer in General Surgery for Dental Students, Mr. C. A. Raison, F.R.C.S.

UNIVERSITY OF LEEDS.

AT the congregation of the University of Leeds on July 1st the degree of Doctor of Science (*honoris causa*) was conferred upon Dr. T. Wardrop Griffith, Professor of Medicine in the University from 1910 to 1925.

The degree of M.D. was conferred upon G. R. Baxter.

UNIVERSITY OF GLASGOW.

A GRADUATION ceremony was held on June 28th. The following degrees were conferred:

M.D.—*J. S. Young, *M.C.*, M. Cohen, J. C. H. Mackenzie.

* With honours.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE trustees announce the award of the Dr. Jessie Macgregor Prize in medical science for the triennial period 1929-31 to Miss Helen M. Russell, M.D., F.R.C.P.Ed., for her record of work on malaria in the Vasiliki Valley, Macedonia, during 1925. The prize was founded in the year 1908 as a memorial to the late Dr. Jessie Maclaren Macgregor of Edinburgh, and is of the value of £75.

ROYAL SOCIETY OF MEDICINE.

ANNUAL MEETING OF FELLOWS.

THE annual general meeting of Fellows of the Royal Society of Medicine took place at the Society's House on July 2nd, under the presidency of Lord DAWSON OF PENN.

The officers of the Society elected for the year 1929-30 were as follows:

President: The Right Hon. Lord Dawson of Penn.
Honorary Treasurers: Dr. A. M. H. Gray and Mr. Girling Ball.
Honorary Secretaries: Mr. E. K. Martin, Dr. G. Riddoch.
Honorary Librarians: Dr. W. Bulloch, F.R.S., Mr. H. W. Carson.
Honorary Editors: Dr. Hugh Thursfield, Mr. Swift Joly.

Other members of Council: Dr. Elizabeth Bolton, Dr. J. S. Collier, Dr. T. W. Eden, Mr. C. H. Fagge, Dr. J. Fawcett, Mr. Sampson Handley, Sir Stanley Hewett, Mr. R. E. Kelly, Mr. Hugh Lett, Mr. V. Warren Low, Dr. A. E. Russell, Sir StClair Thomson, Sir John Thomson-Walker, Dr. H. Letheby Tidy, and Sir William Willcox.

The HONORARY SECRETARY (Dr. Letheby Tidy), submitting the report of the council, said that there were 4,300 Fellows—the highest number reached since the formation of the Society; in 1920 the number was 3,600. Regret was recorded at the death of Sir C. S. Tomes, Professor F. Widal (Paris), and Professor von Pirquet (Vienna), Honorary Fellows of the Society. Professor J. S. Haldane and Professor Ludwig Aschoff were nominated by the council as Honorary Fellows. Mr. Fagge, Dr. Tidy, and Dr. Eden are relinquishing their respective posts as treasurer, secretary, and editor.

On the initiative of Mr. Geoffrey Edwards, the secretary of the Society, the library has been equipped with a photostat. This was demonstrated after the meeting. It takes an exact reproduction, either the same size, reduced, or enlarged, of any page or article of a medical publication for dispatch to the provinces or abroad on the application of a member, without in any way depleting (as when a publication is lent) the issuing library, and thus enabling the library to fulfil its prime purpose—that of reference to those actually using the library on the premises. Within forty-five minutes such a demand was ready for post.

Members of the Society resident in Sydney had made application, with other medical men there, to be allowed to form a Section of the Society in the Commonwealth of Australia. This will be carefully considered by the council; it is the first application of the kind.

Reference was also made in the report to the National Radium Fund, and to the letter which was issued to the nation appealing for money for this purpose. Speaking on this subject at a later stage in the proceedings, the President said that the Fund would be incorporated under Royal Charter, which would secure a considerable measure of independent administration. He hoped that before next session the Fund would exist in fact and in form.

The reports and accounts were unanimously accepted. All the retiring honorary officers were cordially thanked by resolution, and high tribute was paid to Mr. Edwards, the secretary, and his staff for their loyal and ungrudging service during the period under review.

Medical News.

HER MAJESTY THE QUEEN addressed the following message of goodwill to the National Baby Week Council on the occasion of the thirteenth National Baby Week, which, as already noted in our columns (May 18th, p. 925) began on July 1st: "As Patron of the National Baby Week Council I desire, on this its thirteenth anniversary, to convey to one and all connected with the council my very great appreciation of the valuable work and support that is being both carried out and given on behalf of the motherhood and child life of the nation. It is with great interest that I learn of the decision of the council to select three aspects of maternity and child welfare for special study and propaganda during the coming year, and I hope that the council's efforts will meet with all success."

THE annual meeting of the Poor Law Medical Officers' Association will be held in the Holborn Restaurant on Thursday next, July 11th, at 6.30 p.m. The President, Sir Arthur Newsholme, K.C.B., M.D., will give an address on "Some Continental methods of medical relief." The meeting will be followed by an informal dinner (morning dress). Any Poor Law medical officer will be welcome to the meeting and dinner, particulars of which may be obtained from Mr. F. Greenwood, Bank Chambers, Stoke Newington, N.

SIR THOMAS LEWIS will give the third Victor Horsley Memorial Lecture at University Hospital Medical School, Gower Street, W.C., on Tuesday, July 16th, at 5 p.m. The subject of the lecture is "Observations relating to the mechanism of Raynaud's disease." Admission is free on presentation of visiting card.

THE next meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, Cavendish Square, W., on Tuesday, July 9th, at 4 p.m., when Mr. W. McAdam Eccles, M.S., F.R.C.S., will deliver his presidential address on some gaps in the study of inebriety. After the address a discussion on the toxic effects of methylated spirits and impure forms of alcohol will be opened by Sir William Willcox.

A CLINICAL meeting will be held at the East London Hospital for Children, Shadwell, E., on Wednesday, July 10th, when Mr. K. J. Acton-Davis will give an address on the surgical treatment of rickets, with illustrative cases. Tea at 4 p.m., meeting at 4.15 p.m. All medical practitioners are cordially invited.

THE fifth annual meeting of the National Institute for the Deaf will be held at Caxton Hall, Westminster, on Thursday, July 11th, at 3.30 p.m., with the president, Lord Charnwood, in the chair. The main resolution will be proposed by Mr. Somerville Hastings, F.R.C.S., M.P., in the following terms: "That having regard to the grave social and industrial hardships caused by deafness in the lives of large numbers of adolescent and adult persons who were born deaf or have become so, and to the fact that no official inquiry into the results (in the terms of improved social and industrial well-being) of large public expenditures in their education has ever been held, this meeting is strongly of opinion that the time has arrived when a complete investigation into the conditions and needs of these deaf and dumb and deafened persons should be made. And, further, that this meeting urgently calls upon the Government to make such an investigation by means of a Departmental Committee, or otherwise, at an early date."

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Mr. Laming Evans will give a demonstration from 1.30 to 4 p.m., on July 8th, at the Royal National Orthopaedic Hospital, and Major Corbett will give a venereal disease demonstration, at 3 p.m., on July 9th, at the London Lock Hospital (Dean Street branch). Both demonstrations are free. There will be an afternoon course at the Hospital for Diseases of the Skin, Blackfriars Road, S.E.1, from July 8th to 19th; fee £1 1s. From July 22nd to 26th a course on gastro-enterology will be given at the Prince of Wales's General Hospital in conjunction with the North Middlesex Hospital; fee £3 3s. From July 29th to August 24th a course in urology (afternoons and evenings) will be held at the All Saints' Hospital; fee £2 12s. 6d. From August 12th to 24th the Queen's Hospital for Children honorary staff will undertake a half-day special course; fee £3 3s. An intensive course will be given at the Queen Mary's Hospital, Stratford, E.15, in medicine, surgery, and the specialties from August 26th to September 7th; fee £3 3s. In addition to the special courses the Fellowship of Medicine provides a "general course," which consists of the clinical practice of the associated hospitals. Tickets from one week to one year (fees £2 2s. to £21) are issued which entitle the holder to attend at the times stated in the programme provided. The course is continuous and may be begun on any day of any week. Copies of syllabuses of the special courses for 1929 and detailed information concerning the general course may be had from the Secretary, Fellowship of Medicine, 1, Wimpole Street, W.1.

THE Glasgow Post-Graduate Medical Association has arranged a general medical and surgical course from August 19th to September 13th. The fee is £10 10s. for the full course, or £6 6s. for the first or second fortnight. Syllabuses and further information may be obtained from the Secretary, Post-Graduate Medical Association, The University, Glasgow.

THEIR Royal Highnesses the Duke and Duchess of York will visit the Papworth Village Settlement on the afternoon of July 23rd, and later the West Cambridgeshire Flower Show, to be held in the grounds of Papworth Hall.

WE are glad to be able to correct the statement made last week that Sir Ronald Ross was in a very weak state of health on June 21st, when he received gold medals from two societies. Apart from the persisting paralysis, Sir Ronald Ross is very well now, but he makes it a rule not to speak in public. He was obliged to leave the meeting of the West London Medico-Chirurgical Society in order to receive the Manson gold medal from the Royal Society of Tropical Medicine.

THE Patents Committee, under the chairmanship of the Right Hon. Sir Charles Sargant, has begun its investigations, and persons and associations who wish to submit suggestions or to give evidence before the committee are invited to communicate with the secretary, Mr. R. W. Luce, Industrial Property Department, Board of Trade, 25, Southampton Buildings, W.C.2.

WE have published in recent issues lists of medical practitioners serving as members of local authorities or their subsidiary bodies in Great Britain. Notifications have since been received that Sir Harry Waters, honorary pathologist to the Stroud General Hospital, is a member of the Stroud Board of Guardians and a councillor on the Stroud Urban District Council; that Mr. H. D. Levick, F.R.C.S., and Mrs. Minnie Levick, M.D., are members of the county borough of Middlesbrough; and that Dr. A. S. Robinson is a member of the North Riding County Council and the Redcar Borough Council.

THE Medical Commissioners of the National Association for the Prevention of Tuberculosis are at present touring Perthshire, Essex, and Herefordshire, carrying out a series of popular lectures and other meetings.

THE centenary of the birth of the famous physiologist Eduard Friedrich Wilhelm Pflüger, the founder of *Pflüger's Archiv*, who died in 1910, was celebrated on June 7th at Bonn, where he was professor for fifty years.

FOR the use of practitioners of actinotherapy the British Hanovia Quartz Lamp Co., Ltd. (Slough), has devised, in a form suitable for filing, cards on which can be recorded the details of treatment for each patient. The price of these cards is 6s. per hundred, post free.

THE Board of Education has issued a revised edition of its list of certified special schools, recognized institutions for the training of blind and other defective students, and nursery schools in England and Wales. The pamphlet may be obtained from H.M. Stationery Office, price 9d. net.

THE eighth international congress of dermatology and syphilology will be held next year in Copenhagen from August 5th to 9th. The subjects announced for discussion are the etiology and pathogenesis of eczema; syphilis: immunity, reinfection, superinfection; and tuberculosis of the skin and its treatment. Those intending to communicate papers are requested to announce their subjects not later than April 1st, 1930, to the secretary-general, Dr. Svend Lomholt, Raadbuspladsen 45, Copenhagen, from whom full particulars of the congress may be obtained.

ACUTE and chronic alcoholism, exclusive of deaths due to poisoning by wood alcohol and denatured alcohol, have caused 175 deaths among the policy holders of the Metropolitan Life Insurance Company of New York during the first quarter of this year, as compared with 144 deaths in the corresponding period of 1928.

THE following appointments have recently been made in foreign faculties of medicine: Dr. Marcel Labbé, professor of general pathology and therapeutics at Paris, has succeeded the late Professor Widal in the chair of clinical medicine; Dr. M. Wertheimer of Berlin has succeeded Professor Schumann in the chair of psychology at Frankfurt; Dr. Hermann Siemens of Münich has been appointed professor of dermatology at Leyden; and Professor Steurer has succeeded Professor Körner as director of the oto-rhino-laryngological clinic at Rostock.

AN institute of physical education connected with the faculty of medicine has been established at the University of Nancy.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

RETROBULBAR NEURITIS?

"NESCIO" (Kilmarnock) writes: A male patient, aged 41, complained of dimness of vision six months ago. An eye specialist diagnosed a retrobulbar neuritis, without cause being found. Treatment, chiefly with potassium iodide and nux vomica for four months, made no difference. The patient was then seen by a neurologist and was under observation in hospital for seven weeks. No abnormality was found in the nervous system or elsewhere. The visual trouble was diagnosed as hysterical. There has been neither improvement nor deterioration in sight. The patient is a healthy, strong, hard-working joiner. Can anyone suggest a diagnosis and treatment of his condition?

PAINFUL HEEL.

DR. J. G. BLACKMAN (Portsmouth), with reference to the query by "Giza" (May 11th, p. 890), writes: I have always regarded this symptom as due to gout, and treatment directed against this condition has, in my experience, usually resulted in its cure, or at least relief.

STIES.

DR. SYDNEY TIBBLES (London, W.) writes: In reply to Dr. J. E. Harford's inquiry (June 29th, p. 1189), may I suggest the administration of yeast, of which there are several tablet forms on the market. This, combined with hot boracic fomentations at night, frequent daily bathings with boracic lotion, and, should matter form, immediate incision of the sty, should effect a cure. It is most important to eliminate any source of congestion of the lid margins which may be caused by a small error of refraction or muscular trouble. Personally, I have found the above line of treatment successful where autogenous vaccines and radiation to the lid margins have failed, but I can offer no explanation as to how this rather old-fashioned remedy acts.

UMBILICAL DISCHARGE.

"B. B. L." writes: In reply to "W. D.'s" inquiry (June 15th, p. 1104), I have been consulted several times by patients about this condition, most of the patients presenting themselves during a spell of intensely hot weather. In all of them the umbilicus had the appearance of a narrow funnel, lined by normal skin, leading obliquely downwards into the abdominal wall. In one case a probe could be passed downwards for about 2 in. The only explanation seems to be that the umbilical cord had become invaginated, and the cut end had formed some attachment in the depths of the abdominal wall. The serous discharge is of a seborrhoeic nature, resulting from the natural skin secretions and bath water, which cannot be reached by a towel (so narrow and deep is the opening). Relief can be obtained by daily cleansing and the use of talcum powder. The patient in which the passage was measured had a laparotomy done for another complaint six months ago, with a long incision curving round the side of the umbilicus. The surgeon reported no abnormality, and as the umbilicus still requires attention one regrets that it was not excised at that time.

INCOME TAX.

Purchase of Practice: Audited Accounts.

"A. C. K." bought a practice as from October 1st, 1928; the inspector of taxes has requested him to arrange for his "account" for his first year in the practice to be prepared by a qualified accountant, and in the meantime to make a "provisional return" of his income.

*** Taking the second request first, a provisional return can, no doubt, be made by entering in the declaration an estimate for the first year based to some extent on "A. C. K.'s" predecessor's earnings. That course may be convenient, as enabling "A. C. K." to make a payment on account of his income tax liability, but, in our view, no compulsion rests on him to make such a return, and he would be legally justified in waiting until after September 30th, 1929, before making his return or paying tax. On the point of employing a qualified accountant to prepare his account, many practitioners find it desirable to do so, in order that their own time may be economized and that no admissible deductions may be overlooked, and presumably the income tax authorities are prepared to put greater faith in the accuracy of accounts prepared by an independent and skilled person. But the inspector of taxes has no right to make that stipulation, and if "A. C. K." prefers, and is competent, to prepare the account himself we suggest that he should do so, and in sending it in should offer to exhibit the bank pass-books, etc., from which it was prepared.

LETTERS, NOTES, ETC.

THE UROLOGICAL SOUND-FILM.

A Disclaimer.

SIR JOHN THOMSON-WALKER writes: At the last meeting of the Urological Section of the Royal Society of Medicine on June 27th I gave, by invitation, a demonstration of motion and sound pictures of operations, and notice of the forthcoming demonstration was published in your issue of the previous week. There has since appeared in the public press a florid account of this demonstration, with personal references to myself, and a statement that I am supposed to have made at an interview. I am writing to assure my professional colleagues that I have had no communication with the press by word or in writing, and that no interview of any sort has taken place. I am taking steps to have this acknowledged by the journal in question.

*** An account of the demonstration appears at page 23 of the present issue. We willingly publish this disclaimer, though no one who knows Sir John Thomson-Walker will need his assurance.

CONGENITAL ABSENCE OF THE BILE DUCT.

DR. S. WAND (Birmingham) writes: The following case is, I think, worthy of mention. A woman, aged 35, has been married twice. By her first husband she had three children, all of whom are alive and well. By her second husband she has also had three children during the last four years. The first was stillborn. The second was a breech case, the child being born alive, but profound jaundice developed on the second day and it died on that day. The third confinement was normal and rapid, the baby being a fine, large, and healthy-looking child. On the second day jaundice developed and the child died on the same day. I made a post-mortem examination and found congenital absence of the bile duct, the duct being nothing more than a fibrous cord. The mother's Wassermann reaction is negative. To me the interesting points are: (1) the familial history; (2) the fact that these cases have occurred only during the second marriage.

DETECTION OF MILK ADULTERATION.

THE freezing point of milk samples has been used since 1893 in Holland as a means of determining whether added water is present, and Mr. A. van Raalte, D.Sc., of Amsterdam, contributes an interesting note on the value of this method to the May issue of the *Analyst*. He states that it is generally agreed, as the result of very prolonged investigation, that normal mixed milk has a freezing point between −0.54° and −0.57° C. Milk with a freezing point nearer to zero than −0.53° C. is taken as indicating adulteration with water. Dr. van Raalte adds that in Amsterdam each year about 30,000 samples of milk are analysed—that is, about one sample for every thirty inhabitants; in 1927 only 2 per cent. of such samples were found to be adulterated with water. The freezing point test is now coming into use in the United States and in Germany, and figures found in both these countries are said to be in absolute conformity with those in Holland. Dr. van Raalte suggests that this method therefore deserves international acceptance.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 48, 49, 52, 53, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *15*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

1. Undulant Fever.

M. JANBON and J. DUPONNOIS (*Arch. Soc. des. Sci. Méd.*, January, 1929, p. 153) report a case of undulant fever of a particularly prolonged and refractory nature, in which cure was obtained by the administration of trypaflavine (gonacrine). The onset was slow, with a typical undulating temperature, profuse foul-smelling sweats, and emaciation. The arthralgias, characteristic of the disease, did not develop till two to four months later. At the end of five and a half months the patient entered hospital complaining of extreme weakness and pains in the lumbar region and legs, especially the right, which were aggravated by pressure, even of the bedclothes. Erichsen's test elicited pain over the left sacro-iliac articulation. There was slight motor deficiency in the right leg; the right patellar reflex was diminished, but the other reflexes were normal. Radiography revealed a marked separation of the left sacro-iliac articulation, ankylosis of the left condyloid articulations along nearly the whole of the dorso-lumbar column, effacement of the intervertebral spaces, and erosion of the fourth lumbar body. The agglutination test was positive in 1 in 200, though *B. melitensis* was not isolated from the blood till about the ninth month. Treatment with the specific vaccine, and infra-red irradiations, caused only slight improvement. Intravenous injections of trypaflavine were then tried (the tenth month of the disease), the commencing dose being 10 cg., which was progressively increased by 10 cg. a dose to 50 cg.; these were given at gradually increasing intervals of one, two, and three days. The usual reactions, such as headache and icterus, followed each injection, but subsided the next day. Manifest improvement commenced after the third injection, and resulted in cure. A year after the onset of the disease there is only very slight pain on pressure over the left lumbar muscles, and elevation of the left iliac crest due to a compensatory scoliosis. *X*-ray pictures also showed improvement in the osteo-articular lesions. M. AUBERT and LISBONNE (ibid., p. 161) also report three cases of undulant fever treated with trypaflavine. This was followed by cure in two cases, but not in the third, owing to incorrect and insufficient treatment.

2. A. V. HARDY (*Journ. Amer. Med. Assoc.*, March 19th, 1929, p. 853), as the result of an investigation of 125 cases of undulant fever that occurred in Iowa between October, 1927, and December, 1928, came to the following conclusions. Most of the patients lived on farms or in country towns; the occupational groups chiefly involved were farmers or packing-house workers. There were no recognized cases among children under 5 years of age, and only a few cases in older children, while the bulk of the cases occurred in men aged from 20 to 45. There was a striking variability in the symptoms and course. Weakness was a constant symptom, and was frequently associated with fever, pain, or rigors. The fever was generally intermittent or remittent, and undulations were not often observed. Physical signs were rarely apparent, the most frequent being an enlarged spleen. There was usually a slight leucopenia and a decrease in the neutrophils. The diagnosis was confirmed by agglutination tests, almost always repeated, and when possible by blood cultures.

3. Nervous Sequels of Serum Injections.

F. KENNEDY (*Amer. Journ. Med. Sci.*, April, 1929, p. 555) records six cases in which nervous sequels developed after the administration of various serums. Four days after prophylactic injection of scarlatinal antitoxin general urticaria developed in a boy aged 12, with a temperature of 104° and symptoms of meningitis. On the third day of serum sickness he became aphasic and had partial right hemiplegia. Two days later he showed bilateral swelling of both discs. The cerebro-spinal fluid escaped under great pressure, but only 14 lymphocytes per c.mm. were present. The symptoms subsided in the next few days, and complete recovery ensued four and a half weeks from the onset of his serum sickness. The second patient, a lad aged 18, three weeks after prophylactic inoculation against scarlet fever had a high temperature, urticaria, and severe pains and swelling in all the large joints. Subsidence of the swelling of the shoulders was followed by atrophy of both deltoids and some wasting of the supra- and infra-scapular muscles on each side. Gradual recovery resulted in the course of a year. Cases 3, 4, and 5 occurred in males aged 12, 15, and 21, one of whom developed deltoid paralysis and the other two serratus magnus paralysis after prophylactic injection of antitetanic serum. The sixth patient was a man, aged 34, in whom, on the day following the third injection of antityphoid vaccine, polyneuritis developed and lasted for eight weeks. Kennedy thinks that toxicity of the serum, or urticarial oedema of the perineural tissue, or a combination of both, was responsible for the symptoms in the first five cases, while the polyneuritis in the sixth case was mainly toxic in origin. He suggests the intravenous injection of sodium carbonate as a preventive method.

4. Encephalomyelitis after Varicella.

G. W. RAKE (*Guy's Hospital Reports*, January, 1929, p. 58), who records an illustrative case, states that a review of the literature shows that cases of encephalitis and myelitis following varicella are sufficiently frequent to exclude the possibility of mere coincidence. Most of the recorded cases have occurred in children up to 8 years of age. This may partly be due to the fact that varicella itself is a disease of childhood, but it seems that if, as in Rake's case, more than one of a family contract the disease, it is the younger member who suffers from the nerve lesion. The incubation period for the nervous complications ranges from five days to about two and a half weeks. The symptoms vary considerably. In many cases the motor tracts are affected and there is upset of sphincter control. In others the anterior horn cells are affected. Sensory changes, such as anaesthesia or hyperaesthesia, have been described. Meningeal symptoms have occurred in some instances. Cerebral symptoms range from hemiplegia to the generalized tremors or nerve palsies. The cerebro-spinal fluid may be normal or show an increase of cells or protein, or both. The prognosis is good. No case has come to necropsy, and in most instances complete recovery ensued. Rake's case was that of a boy, aged 2½ years, who on the third day of varicella became irritable, vomited, and for the next few days was delirious and comatose. He had convergent squint, spasticity of the whole of the left side, increased tendon reflexes, a positive Babinski's sign, and absent abdominal reflexes on that side. A gradual recovery followed.

Surgery.

5. Intracranial Complications of Purulent Otitis Media.

W. C. WARREN, jun. (*Arch. of Surg.*, April, 1929, p. 1552) states that one out of every four cases of chronic infection and one out of every nine cases of acute infection of the middle ear present an intracranial complication, the mortality in each case being high. The symptoms are usually headache, vomiting, vertigo, fever, and disturbed pulse, temperature, and respiration ratio. The slower pulse rate is probably due to toxic irritation of the vagus centre. The three most common types of intracranial complications are lateral sinus thrombosis, abscess of the brain, and meningitis. In cases of lateral sinus thrombosis, chronic mastoiditis and cholesteatomas are the most common causative factors, and the complication occurs most frequently in children with disease of the middle ear complicating an acute exanthem that has caused severe depletion. The typical symptoms are the euphoria and sharp oscillations of temperature, and in 25 per cent. of cases there is a positive bacteriaemia. Leucocytosis with a fairly high polymorphonuclear count is usually present. Treatment, which should be surgical, gives a good prognosis if the tongue is moist and not very coated, and if the temperature comes down by lysis after operation. Abscess of the brain is most commonly caused by purulent otitis media, and the streptococcus is the most usual organism. The majority of abscesses occur near the diseased area of bone forming the pathway of intracranial infection. Headache is the most usual early symptom, with subnormal temperature and slow pulse and respiration: intermittent vomiting is a characteristic sign, with optic neuritis and a coated tongue. Treatment must be surgical to evacuate pus and establish drainage, but the prognosis is poor, with a mortality rate of 40 per cent. Post-operative dangers are meningitis, hernia of the brain, and the spreading of infection. Meningitis is the third type of intracranial complication in purulent otitis media, and the diagnosis of this condition is not difficult. The characteristic symptoms are extreme restlessness, severe headache, picking at the bedclothes, high temperature, with rigidity of the muscles at the back of the

neck, and later photophobia. Lumbar puncture may show cloudy spinal fluid with pus and bacteria, and decrease or absence of sugar. Treatment should be surgical in cases of meningitis which are otitic in origin; it should ensure the removal of all diseased parts contiguous to the meninges, and free exposure of the adjacent dura. For cases of diffuse purulent leptomeningitis the prognosis is bad, as no satisfactory treatment has been found, and death nearly always ensues. Latterly, continuous drainage of the spinal cord by the removal of a lamina and insertion of a drain has been advocated.

6. Simultaneous Occurrence of Fibroma of the Tongue and Larynx.

G. MARTUSCELLI and M. LUONGO (*Arch. Ital. di Otol.*, April, 1929, p. 259) report a case of fibroma of the tongue associated with a similar tumour of the larynx. The patient, who was of good constitution and had an uneventful history, complained of persistent aphonia, which had gradually appeared and been present for about a year. A tumour was found on the left border of the tongue, near the first molar; it was about the size of a large pea, and had a slender pedicle about 3 to 4 mm. long. From its general character and the absence of pain a fibroma was diagnosed; the differential diagnosis from a similar tumour associated with psittacosis is given. This could not be considered to have any relation to the aphonia, but laryngoscopic examination revealed the presence of a small tumour at the anterior attachment of the vocal cords, which was somewhat elongated, about the size of a grape seed, and seemed rather transparent. A cystic fibroma of the larynx was diagnosed. When the laryngeal tumour was excised, a second one, similar in size to the first, was discovered and also removed. Histological examination confirmed the diagnosis. After a review of the literature on the subject, the authors draw attention to the fact that pure fibroma of the tongue is rare; its association with a second fibroma in the larynx or cheek is even more unusual. They consider that the fact of three similar tumours occurring in the same patient raises the question of infectivity, which has already been proved in the case of papilloma.

7. Diagnosis and Treatment of Gaucher's Disease.

R. MÜHSAM (*Med. Klinik*, April 12th, 1929, p. 585) summarizes the characters of this disease as a constitutional affection of the lymphatic and haemopoietic apparatus, with deposits in certain cells of the spleen, liver, lymph glands, and bone marrow of a specific substance (the Gaucher substance) belonging to the cerebrosides, and occurring in characteristic rosette-shaped crystals. Beyond complaining of weakness the patient has no clinical signs until the spleen and liver become enlarged, or there is a tendency to haemorrhages, pains in the bones, bending of the bones, and even spontaneous fractures; pain in the gums which bleed; and sometimes osteomyelitis. The blood picture is not striking; there is a variable anaemia, often some leucopenia, and a diminished number of platelets. The skin assumes a brown subicteric tint. The disease occurs in families, but of the nature of its transmission nothing is known. The diagnosis can be established by examination of the bone marrow from a puncture of the tibia, or of the spleen after removal. All therapeutic measures seem to be useless, but splenectomy relieves the condition and may prolong life for some years.

Therapeutics.

8. Metallic Salt Therapy.

L. E. WALBUM (*Nord. Med. Tidsskrift*, April 13th, 1929, p. 231) reviews the principles of the system of treatment associated with his name. He maintains that it has nothing to do with Ehrlich's chemotherapy, and should not be compared with non-specific therapy such as protein shock. It is, indeed, strictly specific, and it aims at stimulating the body's own defences by means of small quantities of metallic salts. Ten years ago the author began to experiment with the injection of various metallic salts to see if they promoted antitoxin production. He found that, in addition to antibody production, this procedure favoured numerous other processes enabling the body to combat germs and their toxins. The action of the bacteriolytic substances and the phagocytic activities of the leucocytes were multiplied. Experimental animals treated with lethal doses of tetanus, diphtheria, staphylococcal, and dysenteric toxins were cured by a single injection, and in certain cases the internal secretions of the body were stimulated. The first experiments were carried out on mice infected with "ratin" bacilli; forty different metals were tested, and thirty-eight of them were found to be practically inert, but caesium and iridium completely cured the infected animals. Later, rabbits were given intravenous injections of highly virulent tubercle bacilli which invariably caused death of the untreated rabbits in one to four months. Out of forty-two different metals investigated cadmium and manganese were found in almost every case to effect a complete cure. When the small optimal dose was exceeded, however, antibody production was reduced till, after the overdosage had reached a certain limit, it fell below the original base line. Such overdosage might still be far below that which would actually cause metallic poisoning. A comparison of the stimulation curves of agglutinins and amboceptors on the one hand, and of bacterial growth on the other, showed that the latter required a considerably higher concentration of metallic salts than did the former. If the dosage is increased still further, to such a degree that the growth of bacteria is inhibited, the experimental animal usually dies of metallic poisoning. In searching for the optimal dose, Walbum adds, it is better to keep below it than to exceed it, under-dosage never being harmful, whereas overdosage is dangerous. After referring to the application of his system to the treatment of pulmonary tuberculosis, and the experiences in this field of N. Lunde in Norway, the author describes the experiments he is at present conducting at the Serum Institute in Copenhagen with rabbits infected with *Staphylococcus pyogenes aureus* by the intravenous route. Of the twenty-one metals tested, tin and zirconium have hitherto been found to cure the infected animals. During the past four or five years the institute has also been investigating the application of Walbum's system to the problem of cancer.

9. Autohaemotherapy in Nephritis.

G. KOLISCHER (*Journ. Amer. Med. Assoc.*, March 23rd, 1929, p. 968) remarks that, though protein shock treatment is undoubtedly useful in the case of elderly men suffering from urinary retention and nephritis, the employment of milk injections always produces a pronounced general reaction; this is undesirable in view of the fact that in such conditions the heart is always involved to some extent, and any additional strain is inadvisable. The casein derivatives of milk used for the same purpose do not produce the same reaction, but their therapeutic effect is variable. The author, therefore, commends autohaemotherapy as the ideal procedure. With the usual antiseptic precautions, 5 c.cm. of blood in the case of infants, or 10 c.cm. in adolescents and adults, is withdrawn from a superficial vein and immediately reinjected into the gluteus muscle. This treatment is usually given twice a day on two consecutive days, after which a week is allowed for estimation of the results; if continuance of such injections is indicated they are given once a day on every other day. The author records details of five cases selected for autohaemotherapy owing to failure of the routine treatment; in each instance a signal success was obtained. The first patient was a lad, aged 18, who had subacute appendicitis and unilateral glomerulonephritis; the renal condition was entirely cleared up by three gluteal injections. The other cases reported were: nephritis in pregnancy, acute nephritis following tonsillitis in a boy aged 6, and two cases of nephritis with prostatic involvement in patients aged over 60. The author adds that if for any reason autohaemotherapy is not deemed advisable in an infant reduced doses of casein emulsion may be injected hypodermically; it is advisable to await the complete subsidence of a reaction before repetition of the injection. Kolischer suggests that autohaemotherapy should be given an extensive trial in nephritis.

10. Treatment of Disseminated Sclerosis.

J. VITEK (*Bruxelles-Méd.*, May 12th, 1929, p. 805) mentions a considerable number of the remedies, both medical and surgical, that have been used in the treatment of circumscribed sclerosis. With the majority of these he has obtained no favourable results, but he has found *x*-ray irradiation combined with chemotherapy to be more beneficial. The method pursued is first to administer *x* rays, followed by injections, on alternate days, of a colloid silver preparation known as dispargen and mercury cyanide. The silver preparation is injected intravenously, the commencing dose being 3 c.cm.; subsequent doses are progressively increased to 15 or 20 c.cm. until a total of 180 to 200 c.cm. has been administered. The dose of mercury cyanide is 5 to 10 mg. At the same time Fowler's solution in progressive doses is given orally; the initial dose is 5 minims three times a day, and this is increased by 2 minims each time until a total of 90 minims has been given, when it is then similarly decreased. Vitek does not recommend sodium cacodylate or novarsenobenzol. Massage of the lower limbs, passive movements, gymnastics, and tepid baths are adjuvant measures which he finds useful. The massage, baths, and medical treatment should be continued at home, with an occasional one-week's course of colloidal silver (in pills of 0.03 gram), but a second period of institutional

treatment may be useful after some time. Occasionally, especially in very young subjects, the disease may be a manifestation of latent congenital syphilis, and in these cases striking results are obtained by mercury cyanide. Vitek acknowledges that the undoubted benefits obtained by this method may be due merely to spontaneous remissions, but hopes that these remissions occur earlier as the result of the treatment. He adds that women must be warned about the serious consequences of pregnancy as regards the progress of the disease.

Radiology.

11. Ionization Treatment of Chronic Rhinitis.

COLLOT (*La Vie Méd.*, April 10th, 1929, p. 365) points out that many diseases, such as gastritis, appendicitis, and bronchitis, are caused by the ingestion or inspiration of discharges from purulent nasal or buccal conditions, and that the commonest of these causes is chronic rhinitis. The turbinates play a double role in warming the inspired air and in cleansing this air from dust and micro-organisms. In rhinitis these functions are abolished, as the erectile tissue becomes relaxed and paralysed, venous stasis and oedema is established, and the secretion is altered and stopped. Treatment should aim at diminishing the congestion of the mucosa and restoring its tonicity, but as the usual measures tend to destroy rather than repair this membrane they are irrational and abortive. For over eight years Collot has employed a modification of Frieli's zinc ionization method with success. This consists in the application of high-frequency currents, salicylate ionization, and vibratory massage. The high-frequency currents are applied by a MacIntyre electrode of such a form that it can be applied to all points of the mucosa; they have a vaso-constricting and sterilizing action. The duration of each application should be five to ten minutes for each nostril. Ionization is effected by means of strands of absorbent wool impregnated with an isotonic solution of sodium salicylate. These must cover the whole surfaces of the fossae; they are connected with the negative pole of a continuous current battery. An intensity of 2 to 3 ma. should be maintained for twenty to thirty minutes. The vibratory massage, which should be of a short duration of less than a minute, is made by means of absorbent wool, soaked in oil, carried in a holder or forceps. The vibration can be produced manually or an apparatus may be used. The number of treatments varies according to the case, but an average of twenty is usually necessary. These should be given daily at the commencement of treatment, but at longer intervals later; the different applications are made on alternate days, the electrical treatment and massage being employed one day, and the other procedures on the next day.

12. Radium Treatment of Carcinoma of the Buccal Cavity.

G. E. PFAHLER (*Radiol. Rev.*, March, 1929, p. 93) bases his radium technique on the principles laid down by Régaud—namely, (1) that radiation should be prolonged so as to destroy all the cells in the process of division, and (2) that as radiation becomes more penetrating the diffuse necrosing effects diminish and disappear, and there only remain selective effects on cancer cells in the process of division. Inside the mouth the radium is screened by 2 mm. of platinum whenever practicable (the equivalent of about 4 mm. of lead); 1,000 to 3,000 mg. hours are employed, over a period of three to four weeks, at as much distance as the local conditions will permit. Externally, the author uses packs of wax or felt, or both, covered with plaques of 5 mg. or 10 mg. needles screened with 3 mm. of brass. The pack, with from 100 mg. to 300 mg., is applied at 4 cm. distance, generally from each side, and always on both sides in tongue cases. Four twenty-four-hour applications within a month are advocated, equivalent to 20,000 to 30,000 mg. hours. There should be associated treatment for dental caries, pyorrhoea, anaemia, syphilis, or anorexia, when present, and careful attention to the hygiene of the mouth. The advantages claimed are that the treatment is painless at the time of application, though there may be soreness and swelling later; no anaesthetic or hospitalization is necessary, and there is no mutilation or constitutional involvement. Disadvantages mentioned are the necessity for a considerable quantity of radium, the daily supervision of an experienced radiologist, and the constant co-operation of the patient, whose occupation is interfered with for at least a month. Of 56 patients with advanced intra-oral cancer and glandular metastasis treated in private during the last three years the author finds that 36 are still living; 23 of these are clinically cured, while 13 are still under treatment, most of whom the author hopes to cure.

13. Radiotherapy of Cerebral Tumours.

A. BÉCLÈRE (*Journ. de Radiol. et d'Électrol.*, April, 1929, p. 209) observes that adenomata of the anterior lobe of the hypophysis, which comprise about 20 per cent. of all cerebral tumours, respond well to radiotherapy. Moderate doses, well spaced out, give better results than intensive and rapid treatment. Decompressive trephining of the pituitary fossa, by the trans-sphenoidal route, is indicated only when this procedure fails. Of other cerebral tumours some of the gliomas are the most radio-sensitive—those, for example, which are essentially cellular in structure, such as the medulla blastomas and the spongioblastomas. Radiotherapy diminishes hypertension and relieves grave cerebral signs both by destruction of the tumour cells and, through inhibition of the choroid plexus, by checking the secretion of cerebro-spinal fluid. Radiotherapy may therefore be indicated for relief of symptoms even when there is no possibility of a cure by its means. X rays have been found preferable to the gamma rays of radium. The best results have been obtained with very penetrant rays, well filtered, projected from a distance, and directed through several ports of entry over large surfaces. After a primary irradiation of a dose of 500 R units it is recommended that at succeeding sessions, at an interval of not less than forty-eight hours, a dose of 1,000 R units should not be exceeded. Caution is particularly necessary in cases of hypertension where a cerebral decompression has not been done. One danger in the treatment is oedematous hyperaemia, which will depend on the dose given, and especially on the amount of hypertension already present.

14. Multiple Epilation by Diathermy.

K. MEZEI (*Dermat. Woch.*, May 18th, 1929, p. 720) states that epilation by diathermy has hitherto been conducted with only one needle in a needle-holder so that only a single hair could be removed at once. He has now invented a method which obviates the necessity of a needle-holder, and the pain inflicted is very much less than before. The method also enables a larger quantity of hair to be removed. The larger the area to be epilated the greater the number of needles to be applied. The needles are introduced into the hair follicles, the current is turned on and allowed to flow until coagulation is complete, when the hairs are removed by forceps. In spite of the strength of the current the patient does not feel any more pain than on removal of a single hair. The same apparatus can be used for epilation with electrolysis.

Obstetrics and Gynaecology.

15. Pituitary Secretion and Genital Function.

B. ZONDEK (*Zentralbl. f. Gynak.*, April 6th, 1929, p. 834) gives a further account of the preparation and biological properties of the hormone of the anterior lobe of the pituitary, and describes its trial clinically. To this hormone he now gives the less cumbrous name "prolan." With Aschheim he has shown that it stimulates ovarian activity; when injected into immature, as distinguished from castrated, mice or rats it brings about an oestrus. Prolan, unlike folliculin, is destroyed by heat, acids, and alkalis; it is dialysable and soluble in water, insoluble in ether, and precipitated by alcohol or acetone. It has now been prepared in concentrated solution containing five mouse units, corresponding to thirty rat units, per cubic centimetre. In rabbits, Zondek now reports, the action of prolan is specially striking; in infantile rabbits, given about 1,500 rat units in ten days, the uterine cornua are so much enlarged as to suggest pregnancy, and the ovaries are enlarged sixfold, containing large haemorrhagic luteinized follicles. In old mice in which oestrus has long been absent prolan administration restores rut and brings about great ovarian hyperplasia. Mature mice, paradoxically, can be rendered temporarily sterile by prolonged prolan administration, the ovaries being filled with lutein cells, and follicles being almost completely absent. Prolan prepared from the hypophysis of male animals is said to have the same biological action as that made from females, and male animals respond to prolan injections in a manner analogous with females—castrated bucks being unaffected, but infantile ones showing enlargement of all the genitalia, most notably of the seminal vesicles. The effect of prolan has been secured in rats by oral administration; not, however, in mice, which require on injection much larger doses than rats in proportion to the body weight. Women injected with prolan a few days before laparotomy have been found to show hyperaemia of the vagina, uterus, and Fallopian tubes; the intramuscular injection of prolan increases the rectal and vaginal temperature from half to one degree Centigrade above that of the axilla. In three instances after injecting

prolan into women for fourteen days small cysts were found in the ovaries. In endeavouring to restore menstruation by prolan treatment in cases of amenorrhoea (the primary site of stimulation being the ovaries), Zondek states that it is important to distinguish cases of amenorrhoea due to hyperaction from those due to hypoaction of folliculin; this can be done by injecting mice with the urine. In hyper-hormonal cases, which are unsuitable for prolan treatment, greater amounts than one mouse unit of folliculin per 6 c.cm. are present. Hyper-hormonal cases of amenorrhoea, it should be remembered, frequently become spontaneously rectified. Zondek reports the trial of prolan treatment in eight cases of amenorrhoea, primary or secondary. In five patients one or two menstruations followed between seventeen and thirty days after the commencement of treatment; bleeding within a day or two of treatment is not indicative of stimulation of ovarian function, and must be attributed to the vascular congestion in the genitalia which follows prolan administration. In one patient the treatment was ineffective, and in two cases, eight days after a week's prolan treatment, curetting showed hypertrophy and cyst development in the endometrium.

16. Glycosuria in Pregnancy.

E. C. P. WILLIAMS and L. WILLS (*Quart. Journ. Med.*, April, 1929, p. 493) review the alterations occurring in blood sugar curves during pregnancy, as shown by a study of cases at the same stage of pregnancy, and by watching individual cases from the early months to the puerperium. Sugar determinations were made over a period of two and a half hours, and the urine was tested for sugar and acetone at the end of the first and second hours. The patients were tested in the morning four hours after taking a cup of tea and a piece of bread-and-butter, and after a dose of 100 grams of glucose in 200 c.cm. of water with the juice of a lemon. These were compared with the normal curve, range, and average for fifty healthy non-pregnant women. The curves were considered in sections, namely: (1) from the first month to the end of the fifth; (2) from the sixth month to full term; and (3) after confinement. From the examination of forty-three non-glycosuric cases and twenty-one cases of symptomless glycosuria, it was concluded that in all periods of pregnancy and the puerperium the blood sugar curves of normal non-glycosuric patients fall well within the range of curves obtained from normal non-pregnant women, with a tendency to drop as pregnancy progresses, rising in the early puerperium and returning to normal in a few weeks. Probably in all normal pregnant women the renal threshold appears to be lowered. On an ordinary diet the incidence of symptomless glycosuria has been shown to be 5.4 per cent. of all pregnant women, based upon an investigation in 640 unselected cases, and the incidence of renal leaks in normal non-glycosuric pregnant women after 100 grams of glucose is 60 per cent.; it was noted that in no case with a sugar leakage in the early months was there cessation of the leaking as pregnancy progressed. Raised curves were found in the majority of the glycosuric cases and persisted after pregnancy, but in spite of this the authors do not consider that any treatment is required other than the correct spacing of the carbohydrate in the diet, by which means the level of the blood sugar is kept within limits. With proper dieting such simple glycosurias of pregnancy are regarded as of slight significance, since the cases have normal pregnancies and normal children result.

17. Management of the Normal Puerperium.

ACCORDING to H. J. DREW SMYTHE (*Bristol Med.-Chir. Journ.*, Spring, 1929, p. 59) the puerperium ceased to be a normal physiological process when the human race assumed the upright posture, thereby incurring the risk of such uterine displacements as prolapse. He thinks that the ill health often attributed to some one particular confinement is not infrequently the result of imperfect treatment after birth of the child, and he recommends that the utmost care should be employed by the medical attendant at this period. He discusses perineal repairs and commends the use of the abdominal binder. The patient is not kept on her back, but the Fowler position is adopted, so that the lochia may drain away. Attention is paid to the functioning of the bladder and the breasts; in discussing diet he questions the value of stout, which, he thinks, favours the production of adipose tissue rather than an increase of milk. Abdominal muscular exercises are recommended from the fifth day after delivery, together with rest for an hour or two twice a day in the prone position to obviate any tendency to retroversion. After the seventh day the Fowler position is discontinued at night, and from the tenth to the fourteenth day the patient is allowed to sit up out of bed, the binder now being discarded altogether. Before this, however, it is essential to be certain that the uterus can no longer be felt on abdominal palpation, and that the lochia are clear and normal. Abdominal exercises are still continued, even when the patient has begun to sit up. The author gives the caution that the involution process takes from six to eight weeks to complete, and the patient should not lift any heavy weight, especially in a stooping position, for at least two months after confinement.

Pathology.

18. Acute Bartonellosis in Non-splenectomized Mice.

A. LWOFF and A. PROVOST (*C. R. Soc. de Biologie*, May 13th, 1929, p. 8) describe the production of acute infection with *Bartonella muris* in normal mice. During the course of an experimental infection of a mouse with *Schizotrypanum cruzi* numerous bartonella appeared in the blood. The inoculation of a drop of blood from this animal into a normal mouse by the intraperitoneal route succeeded in setting up a bartonella infection, and by passage through a series of mice it proved possible to separate this organism from the trypanosomes, which multiplied less rapidly. At the first passage bartonella was found in the blood from the fourth to the eleventh or from the eighth to the fifteenth day, depending on the mice; but at the second and subsequent passages it was found from the second to the eighth day. The course of infection was as follows. Forty-eight hours after inoculation occasional organisms were found; after three days there was about one red cell in every fifty invaded; after four days one in every six red cells; and after six days every red cell was affected, there being an average of twenty organisms per cell. A few free organisms were found in the plasma. On the seventh day the organisms had greatly diminished in numbers, and showed granular degenerating forms. On the eighth day no more organisms were to be found. It is clear, therefore, that non-splenectomized mice may suffer an acute experimental bartonella infection, lasting for about a week, and terminating by cure. Such mice are henceforth immune, for at any rate some weeks, and their blood is non-infective to fresh animals. The author succeeded in transmitting infection from mice to rats; some of these animals developed an acute infection and died; others were only slightly affected; while others proved resistant. Cultures of bartonella were obtained from the mouse on N.N.N. agar and on Noguchi's medium. The author recognizes three species only: *Bart. bacilliformis*, the cause of Oroya fever in man; *Bart. muris*, the cause of infectious anaemia in rats and mice; and *Bart. canis*, the cause of infectious anaemia in the dog.

19. A Solution Isotonic with Serum.

I. CHRISTENSEN and E. J. WARBURG (*Acta Med. Scand.*, March 30th, 1929, p. 286) have prepared an aqueous solution which contains 11.3 grams of sodium oxalate, 0.315 gram of primary potassium phosphate, and 1.365 grams of secondary sodium phosphate in each litre of water, and is isotonic with serum. The concentration of the cations in this solution is 0.187. By means of it the relative osmotic pressures of the cations in the serum can be determined; the mean error of the method is 0.86 per cent. In a series of 23 normal persons, 15 men and 8 women, determinations were made of the volumes of the same amount of corpuscles in serum and in the isotonic solution; the maximum deviations from the mean value of the relative cation concentration were 3 per cent. and 2.4 per cent. It was found that the erythrocytes shrink when suspended in relatively large volumes of a non-buffered 1.3 per cent. solution of sodium oxalate, if not previously protected against loss of carbon dioxide, and similarly shrink 10 per cent. in a 3 per cent. solution of sodium citrate. No diurnal variation on the cation concentration of the serum could be demonstrated in two experiments, nor was there any variation after a sweating bath. The solution is said to be suitable for determining the erythrocyte volume-index of cutaneous blood by means of van Allen's haemotocrit.

20. Cholesterinaemia in Gastric Disorders.

T. RICOZZI (*Il Morgagni*, March 31st, 1929, p. 657) records eighteen cases of gastric trouble other than gastric ulcer in which estimations of total, free, and combined acidity were obtained according to Topfer's method, and at the same time samples of blood were taken for estimating the cholesterinaemia by Grigaut's method. The author finds that the cholesterinaemia values in the various cases are not constant, and have no relation to the hydrochloric acid percentages in the gastric contents. The hypercholesterinaemia met with in some cases appeared to be attributable to other organic conditions, such as age and arterio-sclerosis.

" ..... In March I was suddenly attacked with acute pain in the region of the right sacro-iliac synchondrosis. I was helped into bed and could not turn round even to feed myself. Sleep was only obtained by opiates. I saw a leading London Specialist, who tried drugs galore—Radiant Heat, Diathermy, Massage, Ionisation, and Blister. The relief was only very slight, and at the end of three weeks in bed I took Agotan tablets with, I confess, little hope of being any good. The drug acted like a charm, and in about a week or ten days I was able to walk about and see my patients. Last month (April) I had a slight return, but after taking 12 tablets I had no further trouble. I have a patient who has suffered from rheumatoid arthritis for three years and can hardly walk across the room. Her age is 75. She has been taking Agotan for the past six weeks and reports freedom from pain and slight improvement in locomotion. I consider it a most invaluable drug and I shall never be without it."

(Signed) .....,
L.R.C.P.I., L.R.C.S.I., etc.

The above letter, entirely unsolicited, from a London medical man shows the value of HOWARDS' AGOTAN in GOUT, RHEUMATISM, NEURITIS, ARTHRITIS, LUMBAGO, SCIATICA, GOUTY SKIN DISEASES, &c., where caused by excess of Uric Acid.

HOWARDS' AGOTAN is an excellent remedy for these diseases both in private and N.H.I. practice. The cost per head of treatment over a period is considerably less than other remedies when results are taken into consideration.

HOWARDS' AGOTAN is obtainable in Tablets, 7½ grains; in bottles of 25, 50, and 100; in 1-oz. bottles of Powder; and in tubes in a form suitable for local application.

Any reputable Wholesale House can supply or obtain.

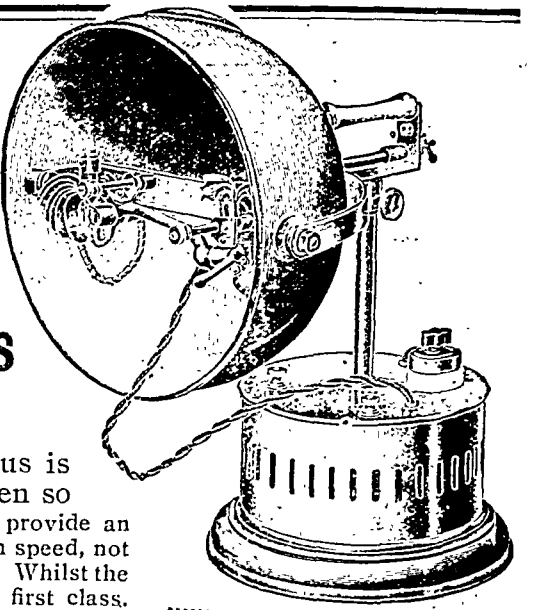
"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.



Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: **30 TREATMENTS 3d.**

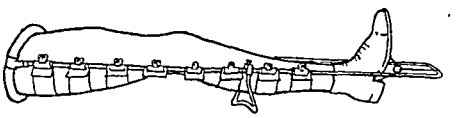
AGENCIES FOR THE COLONIES OPEN.

COLLENDER'S SPLINTS

(Patented in many Countries)

Combine the advantages of the Thomas Splint with many improvements and additions.



They are supplied in fitted cases. The larger set provides material for treating ten fractures simultaneously.

Advantages:

They ensure accurate extension and safe transport. They are adjustable to any length of limb. All parts are interchangeable, standardised, numbered, and replaceable. Being made of metal—Duralumin—they combine great strength with very light weight. They are untarnishable, and can be immersed in sterilizing fluid without injury. They can be used repeatedly.

Invaluable for

Hospital Emergency work, particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-Irritant.

Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 12/- bottles.

Special Terms to Hospitals.

Test sample and literature sent post free on application to:

A. DEHEZ, SURBITON, SURREY.

HARROGATE

is one of the finest SPAS and HEALTH and PLEASURE RESORTS in EUROPE.

AS a HEALTH and PLEASURE RESORT it is famed for its remarkably pure and bracing air, its fine shops and residences, its open spaces, parks, high-class amusements and entertainments, and last, but not least, its ideal situation as the centre of some of England's most glorious countryside.

As a SPA it claims supremacy over all the Spas of the world by virtue of having no fewer than 88 different mineral waters, and a most elaborate and completely equipped Bathing Establishment, with a Staff of upwards of 200 Medically Trained and Medically Certificated male and female Nurses. It is really a compendium of the World's Spas.

Cases treated with benefit comprise:

(1) Gout and other metabolic disorders (glycosuria, obesity).
(2) Functional liver derangement and early cases of cirrhosis, cholelithiasis, and cholecystitis.
(3) Chronic skin diseases of all kinds.
(4) Synovitis, fibrositis, sciatica, and other forms of neuritis.
(5) Arthritis (rheumatoid, chronic rheumatic, and toxæmic varieties).
(6) Mucous colitis, chronic dysentery, constipation, and intestinal toxæmias.
(7) Anæmia in its various forms.
(8) Nervous diseases (neurasthenia and hysteria).
(9) Hyperpiesis.
(10) Sequelæ of tropical diseases, especially anæmia.

Pullman and Fast Restaurant Car Trains daily from King's Cross Station, London. Members of the Medical Profession are asked to write for particulars of Complimentary Facilities to F. J. C. BROOME, *General Manager*, 38, The Royal Baths, Harrogate.

THE BRITISH SANATORIUM, MONTANA sur/Sierre, SWITZERLAND.

Opened on January 1st, 1929, for the treatment of PULMONARY TUBERCULOSIS: English Nursing Staff. Inclusive terms from 7 guineas a week. *Medical Superintendent:*

Hilary Roche,

M.D. (Melb.), M.R.C.P. (Lond.), Tuberculous Diseases Diploma (Wales); Formerly H.P., Brompton Hospital, Medical Supt., Palace Sanatorium, Montana.

URSULINE CONVENT, WESTGATE-ON-SEA, KENT.

A High Class BOARDING SCHOOL is conducted here by the Ursulines of the Roman Union.

The School is situated in its own extensive and beautiful grounds, in a neighbourhood renowned for its bracing and healthy air.

UNIVERSITY of CAMBRIDGE.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY (D.M.R. & E.).

The Course of study for the Diploma, which is open only to duly qualified medical men and women, begins on October 1st, 1929, and occupies nine months. The examinations consist of three parts:

1. Physics, with examinations in January and April.
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a thesis or exercise which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

The first three months may be spent either in Cambridge, where the Physics is done in the Cavendish Laboratory and the Radiology and Electrology in a specially equipped Department of Radiology, or in London, where the Physics is done in the Laboratories of the Middlesex Hospital and King's College and the Radiology and Electrology is taught at the British Institute of Radiology. These Courses run concurrently in Cambridge and London.

The second three months must be spent in London, where courses of lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching hospitals.

The third three months may be spent in recognized hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

Further information as to the Courses may be obtained from:

G. STEAD, M.A., Secretary for the Diploma, and Lecturer in Physics as applied to *Medical Radiology, Cavendish Laboratory*, Cambridge.

A. E. BARCLAY, O.B.E., M.A., M.D., Lecturer in Radiology, Department of Radiology, Medical School, Cambridge.

The Director of the British Institute of *Radiology*, 32, Welbeck St., *London*, W.1.

University of Birmingham.

WALTER MYERS TRAVELLING STUDENTSHIP.

(For Research in any branch of Pathology approved by the Selection Committee.)

The Walter Myers Travelling Studentship is of the value of £300 for one year, and is tenable at a University or Hospital not in Great Britain or Ireland, approved of by the Selection Committee.

The Studentship is available for year 1929-30.

Candidates, who must be under 30 years of age, may be of either sex, and must be Graduates of the University of Birmingham or of some other University in Great Britain or Ireland. In the case of Graduates of other Universities, candidates must have been students of the Birmingham Medical School for three years immediately preceding their application for the Studentship.

The holder of the Studentship will be required to devote his or her whole time to research.

Further information may be obtained from the Dean of the Medical Faculty, University, Edmund Street, Birmingham. Applications must be lodged with the Dean not later than September 2nd, 1929.

C. G. BURTON, Secretary.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1929. Applications should reach the War Office not later than July 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
			150	1st
Lieut.		500	150	2nd
			150	3rd
Capt.			150	4th
	(i) During first 3 years' service as Captain	650	£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£30	11th
				12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 21 years' total service	1300	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

County Council of Middlesex.

TUBERCULOSIS MEDICAL OFFICER.

The County Council invite applications for the post of Tuberculosis Medical Officer. Salary £750 per annum, rising by annual increments of £50 to £1,000 (no bonus), together with out-of-pocket travelling expenses.

Candidates must be registered medical practitioners of not less than 25 years of age, who have held resident appointment in a General Hospital for at least six months, and have had special practical experience in the diagnosis and treatment of tuberculosis in sanatoria or otherwise.

The officer appointed will be required to devote his whole time to his official duties, to work under the administrative control of the County Medical Officer of Health, to reside in such district as may be required, to pass such medical examination as the County Council may direct, and to contribute to the County Council's superannuation fund.

The duties will include the charge of tuberculosis dispensaries, the general arrangement for the treatment of tuberculous patients otherwise than in sanatoria, and such other duties of a similar nature as the Council may direct.

The appointment will commence on October 1st, will be during the pleasure of the Council, and subject to one month's notice on either side.

Applications, setting out (1) age, (2) qualifications, (3) experience, and (4) past appointments, together with copies of three recent testimonials, must be received by the undersigned not later than July 13th. No special application forms are provided. Canvassing will disqualify.

ERNEST S. W. HART.,
Clerk of the County Council.
Middlesex Guildhall, Westminster, S.W.1.
June 24th, 1929.

Rhondda Urban District Council.

ASSISTANT MEDICAL OFFICER.

The above Council invite applications from [illegible] titioners to act as [illegible] AL OFFICER OF [illegible] HOOL MEDICAL supervision, and [illegible] edical Officer of Health, at a salary of £600 per annum, together with travelling expenses necessarily incurred in the performance of the duties.

Candidates must have had not less than three years' professional experience subsequent to registration, and the possession of a Diploma in Public Health is desirable.

The duties will pertain to both public health and school medical services, but experience in the work of school clinics, including the examination and certification of defective children, orthopaedic work, and the prescription of glasses for errors of refraction, will be considered to be of special importance.

The appointment will be subject to two calendar months' notice on either side, and to the approval of the Board of Education The officer appointed will be required to reside within the Rhondda Urban District, and will not be allowed to engage in private practice.

Canvassing by or on behalf of candidates will be considered to be a disqualification.

Applications are to be made on forms obtainable from the Medical Officer of Health, Tydfil House, Llewellyn Street, Pentre, Rhondda, by whom they must be received, endorsed "Assistant Medical Officer," and accompanied by copies of three recent testimonials, not later than the first post on Wednesday, July 17th.

The Council Offices, D. J. JONES,
Pentre, Rhondda. Clerk of the Council.
June 29th, 1929.

County Borough of West Ham.

PLAISTOW FEVER HOSPITAL.

SECOND ASSISTANT MEDICAL OFFICER (male) required. Appointment will be for one year. Salary £300 per annum, with board, residence, and laundry. Preference will be given to candidates who have held a resident appointment in a General Hospital. Good facilities for post-graduate study, such as the D.P.H.

Applications, with copies of three recent testimonials, to be sent to the Medical Supt., Plaistow Fever Hospital, London, E.13.

St. John's Hospital, Lewisham,

S.E.13.

Applications are invited for TWO MALE RESIDENT HOUSE APPOINTMENTS, for a period of 3 months commencing on August 1st. Salary for each, £100 per annum. Successful applicants must apply for a further term of duty in the next senior appointment for 3 months beginning November 1st. Applications, with copies of testimonials, should reach the Secretary not later than Wednesday, July 10th.

Birmingham Union.

SELLY OAK HOSPITAL.

CASUALTY OFFICER (MALE).

Applications are invited from fully qualified medical practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynaecological, Obstetrical, Children, and Infectious sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-Therapeutic, Massage, and Sunlight Departments. Over 2,500 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The person appointed will be required to assist at operations, administer anaesthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. S. KELMAN, M.B., F.R.C.S. (Eng. & Edin.), at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Friday, July 12th.

Union Offices, C. P. BEECH,
Edmund Street, Clerk to the Guardians.
Birmingham.
June 21st, 1929.

The Urban District of Weston-super-Mare.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council invite applications for the position of Medical Officer of Health and Medical Superintendent of the Isolation Hospital.

For the present the appointment will be a part-time one, but it is hoped that further Public Health work will become available in the near future.

The gentleman appointed will be precluded from engaging in general practice, but will be given opportunity for doing other remunerative work

Applicants must be registered Medical Practitioners, holding a qualification in Public Health or State Medicine. Previous experience in school medical work is desirable.

The appointment will be subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, and the duties will be those prescribed by the Order, and such other duties as are or may be imposed by the Council Any other work or duty proposed to be undertaken to be subject to the approval of the Council.

Commencing salary £600 per annum, payable monthly.

Office accommodation and staff are provided by the Council.

The office is an established post under the Local Government and Other Officers Superannuation Act, 1922.

Personal canvassing of members of the Council, either directly or indirectly, will be a disqualification, but 24 copies of the application and testimonials may be sent to me for the use of the Council.

Applications, on forms to be obtained from the undersigned, endorsed "Medical Officer of Health," and accompanied by copies of three testimonials of recent date, must be forwarded to me before July 15th next.

SYDNEY C. SMITH,
Town Hall, Clerk to the Council.
Weston-super Mare.
June 20th, 1929.

Princess Louise Kensington

HOSPITAL FOR CHILDREN,
North Kensington.
(42 Beds pending completion.)

The Board of Management invite applications for the post of HON. RADIOLOGIST. Candidates must be registered medical practitioners, and it is desirable that they should hold the D.M.R.E.Camb

At least one attendance weekly will be necessary. Further details should be obtained from the Secretary, Princess Louise Kensington Hospital for Children, St. Quintin Avenue, W.10, and formal applications should be sent in not later than first post on Thursday, July 25th.

Devon County Council.

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

The County Council invite applications from duly qualified medical men holding a Diploma of Public Health, of not more than 45 years of age, for this appointment.

The salary will commence at the rate of £1,200 a year, with four annual increments of £50 to a maximum of £1,400.

The officer appointed will be required to devote the whole of his time to his official duties, to provide his own motor car and use the same when necessary in the discharge of his duties, for which he will be allowed expenses in accordance with Grade A of the Council's scale. He will also be allowed the usual subsistence allowance and for necessary journeys by rail.

The appointment has been designated an established post under the Local Government and Other Officers Superannuation Act, 1922.

Applications on the prescribed form, to which are attached a general statement of the conditions of appointment and the duties, can be obtained from me, and must be returned, accompanied by copies of not more than three recent testimonials, so as to reach me not later than the first post on July 16th next.

Personal canvassing by or in favour of a candidate will disqualify, but a candidate may, if he wishes, send me 40 copies of his application for the use of the Committee.

The officer appointed will be required to take up his duties on December 1st next.

The Castle, BRIAN S. MILLER,
Exeter. Clerk.
June 24th, 1929.

City and County of Kingston upon Hull.

HULL MATERNITY HOME AND INFANTS' HOSPITAL.

RESIDENT MEDICAL OFFICER (WOMAN).

The Corporation of Hull invites applications from unmarried or widowed Registered Medical Practitioners, under the age of 40 years, for the appointment of Resident Medical Officer (Woman) at the Maternity Home and Infants' Hospital, Hedon Road, Hull. Candidates must be of at least three years' standing in their profession.

Salary £450 per annum, together with board, washing, and residence at the Maternity Home. The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applicants must have had post-graduate experience in obstetrics, paediatrics, and the treatment of venereal disease in women.

The successful candidate will be required to devote the whole of her time to the duties of the appointment, which will also include attendance, when required, at Ante-Natal, Post-Natal, and other clinics.

Particulars of the duties and forms of application may be obtained from the undersigned.

Completed applications (in an envelope endorsed "Resident Medical Officer, Maternity Home"), together with copies of three recent testimonials, must be received not later than Thursday, July 18th.

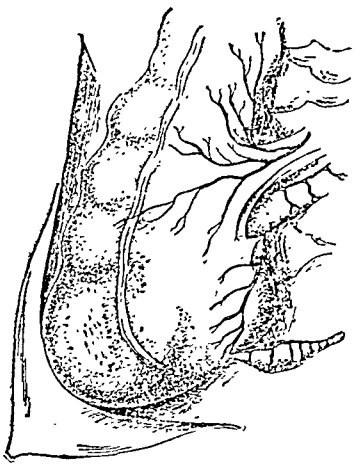
24. CARDIFF. — Good-class old-established non-dispensing PRACTICE, worth last year about £1,350, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, freehold, £2,000. Prem. £2,000.
25. SOUTH LONDON (Near CROYDON).—Sound and increasing mixed-class PRACTICE, in growing locality. Gross cash receipts for immediate past 12 months £2,800, including panel of 2,240. Fees 2/6 to 7/6. Convenient freehold house, with electric light. Garage. Garden. Good sport and schools. Premium £4,500. Efficient introd.
26. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established good mixed non-panel Practice, offering large scope. Receipts for last year nearly £2,300. Fees 2/6 to 7/6. Little midwifery. Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
27. NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, mileage extra. No dispensing. Excellent Bungalow residence, in an acre of garden, with fruit trees, tennis court, etc., containing 9 rooms, bathroom, etc. Electric light, h. and c. water. Climate finest in New Zealand. Splendid educational facilities and unlimited sport. Scope for surgery.
28. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable qualified man possessing the F.R.C.S. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation at present held on lease with option to purchase. Premium 2 years' purchase.
29. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE.—Large Hospital Town within 80 miles of London. A well established connection averaging nearly £1,000 p.a. (last year £1,059). Patients upper and middle-class. Fees 1½ to 15 gns. House in pleasant position, with ample professional accommodation. Rent £60. Premium £1,500, or offer. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital and successor will be appointed.
30. LIVERPOOL.—Mixed-class PRACTICE, producing this year at the rate of over £1,200. Panel of 560. Good house specially built and well situated, containing 2 reception, 4 bedrooms, etc. Large garden. Garage. Price for freehold £1,800, part on mortgage. Prem. £1,650.

Full Schedule of Terms and Conditions will be forwarded on application.

Among the Results of Constipation



Distended and sagging cæcum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxæmias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL Brand Compound, combining three essential actions: lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted fæces, generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol Brand Compound assists the organism back to regular normal evacuation by restoring *peristaltic function.*

The dependability of Agarol Brand Compound has definitely enlisted the interest of the medical profession, who in most cases of acute or chronic constipation, successfully prescribe Agarol Brand Compound — one tablespoonful on retiring.

A Liberal Quantity For Trial To Physicians

FRANCIS NEWBERY & SONS, LTD.
31-33 BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has [illegible]

Perfect [illegible]; pleasant flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Reliable Pituitary Products

THE RESULT OF OVER 20 YEARS OF CONTINUOUS RESEARCH WORK

PARKE, DAVIS & Co., were the first to place a reliable extract of the posterior pituitary gland at the disposal of the medical profession. Since that time, over twenty years ago, the firm's research workers have paid especial attention to this gland. As a result it can be claimed that Pituitrin—the P., D. & Co. pituitary extract—is unrivalled for purity and potency. It is practically free from histamine and relatively free from protein.

¶ For many years the P., D. & Co. research staff had been confident that there were at least two, and possibly more, active principles in the posterior pituitary gland. In consequence, Pituitrin has for long been standardised both on its oxytocic effect and on its blood-pressure-raising activity.

¶ Eventually the discovery and separation of two hormones of the posterior pituitary was made by a group of workers in the P., D. & Co. Research Department and announced in a communication made to the American Chemical Society in September, 1927. These two principles are now available for general medical use under the titles Pitocin and Pitressin.

Pitocin represents the oxytocic principle of the pituitary gland and is standardised to the same degree of oxytocic activity as Pituitrin, namely 10 units per c.c.

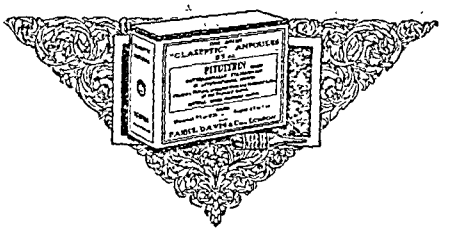
Pitressin represents the pressor principle and is standardised to a pressor activity equivalent to *twice* that of Pituitrin. Pitressin thus represents 20 pressor units per c.c., as compared with 10 pressor units per c.c. of Pituitrin.

¶ The relative spheres of usefulness of the three products may broadly be summarised as follows:—

PITUITRIN may be used in uterine inertia (the exception being complete inertia) with normal or subnormal blood-pressure; in post-operative intestinal distension; and in dysuria.

PITOCIN may be used in cases of uterine inertia even when associated with high blood-pressure *e.g.* eclampsia.

PITRESSIN may be used for the treatment of post-operative shock; in diabetes insipidus; and whenever it is desired to raise the blood-pressure.



A BOOKLET has just been completed giving details of the separation of these active principles and the clinical applications of Pitocin, Pitressin and Pituitrin. This will be sent to any member of the medical profession on request.

Toast *and* Toast Racks superseded

The "RYVITA RACK" has displaced the old-time toast rack

Every day, more and more people are discovering how much more delicious, how much better than toast is "Ryvita Crispbread," the wonderful daily bread of Sweden.

"Ryvita" is made of rye—and nothing but rye—the only cereal from which this the true Crispbread can be made. The first people in this country to eat it were those most highly qualified to judge food values—doctors, dentists, and dietetic experts. "Ryvita" reached the multitude by way of the specialist, thus—despite envious imitators—establishing here "The Ryvita Crispbread Habit."

Eaten as your Daily Bread—"Ryvita," the Veritable Bread of Life, helps to make indigestion, constipation, malnutrition, and obesity unknown. Yet . . . so unique is this wonderful bread, that it is practically impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade. Notice how it sustains without cloying . . . how it gives you an exhilarating sensation of well-being and clear-headedness . . . how you work better, play better, and feel better on "Ryvita."

You will then understand why the old toast rack is now the "Ryvita" rack.

Send a postcard for generous FREE Sample to the Ryvita Company 413, Ryvita House, 96, Southwark Street, London, S.E.1. Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb., 10d.

Makes you fit— RYVITA CRISPBREAD Keeps you slim

Army Health in India

HYGIENE AND PATHOLOGY

By Lt.-Col. JOHN MACKENZIE, M.A., M.B., Ch.B, D.P.H., Royal Army Medical Corps. With a Foreword by Lt.-Gen. Sir MATTHEW FELL, K.C.B., C.M.G., F.R.C.S., K.H.P., Director-General, Army Med. Services. 10/6 net, post free 11/-.

Lt.-Gen. Sir Matthew Fell in his Foreword says:

"It is my hope that his work may be read, not only by officers of the Military Medical Services, British and Indian, but by all those medical men, wherever they may be, whose lot is cast under the 'burning implacable sun' of the tropics."

"It is founded on a study of the records of disease and of the application of measures of preventive medicine to the social life of the soldier in India."

Prospective
Students of Medicine

FOR the guidance and assistance of those wishing to enter the Medical Profession, and for those already qualified who are desirous of planning a career, it has been decided to publish, on

August 31st,

a

Special Educational Number

of the

British Medical Journal

THIS Number will contain full information regarding Medical Education and the fees charged by the teaching and examining bodies in England, Scotland, and Ireland. Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

Announcement by the British Medical Association

THE

MEDICAL INSURANCE AGENCY

has arranged

LIFE and ENDOWMENT, EDUCATIONAL ENDOWMENTS, CHILDREN'S DEFERRED ASSURANCES, &c., on behalf of members of the profession for Sums Assured totalling over

ONE AND THREE QUARTER MILLION POUNDS.

If you are contemplating effecting any policy write the Agency, which will be pleased to give you a considered opinion.

The Agency has also arranged the

"Doctor's Special Policy"

(Underwritten at Lloyd's)

for the **Insurance of Cars.**

Comprehensive "Cover." Moderate Premiums. Security.

SPECIAL RATES FOR MORRIS CARS.
BONUSES FOR NO-CLAIMS ALLOWED ON TRANSFER.
SPECIAL COMPENSATION CLAUSE. AGREED VALUES WHERE DESIRED.

Write for a prospectus, stating **Make of Car, Horse-power, Date of Manufacture, and Present Value,** when a quotation will be sent you.

Household, Fire, Accident, &c., Insurances
under comprehensive policies, giving full protection.

What the Agency has done for the Profession:

Saved by way of Rebates on Premiums = over £33,000
Contributed to the Medical Charities = = over £22,980

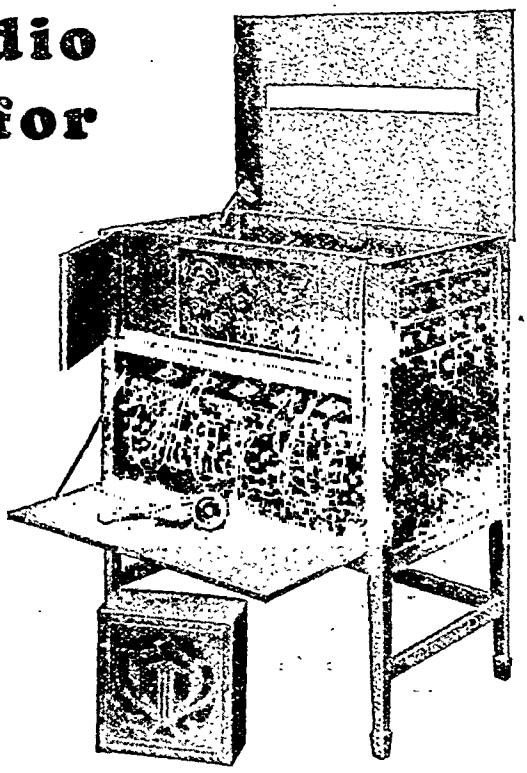
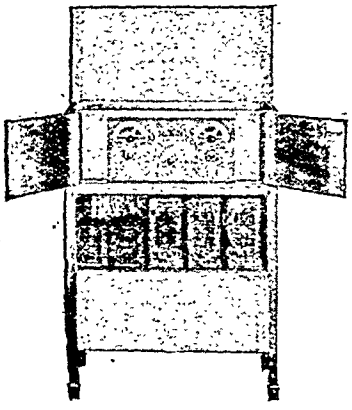
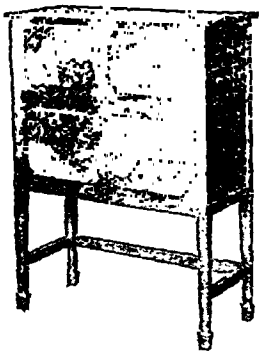
An Ideal Radio Installation for Hospital Entertainment



The Lodge Moor Hospital 9-Valve installation open, showing compact arrangement of eliminators, controls, etc.



Front View of a 6-Valve Met-Vick Hospital Set.



Met-Vick Hospital Set closed, showing attractive, substantial cabinet.

The above illustration shows the Met-Vick Set supplied to the Lodge Moor Hospital, Sheffield. It is capable of operating 40 loud speakers, and 450 pairs of headphones, and is operated direct from the electric light mains.

Met-Vick Hospital Sets can be supplied for operation of any number of loud speakers and phone points with controls which enable the complete installation to be started up or shut down, or alternatively, individual sections may be controlled without interference with the rest of the installation.

There is no trouble from Batteries or Accumulators, all current being supplied direct from the Mains through Met-Vick L.T., H.T. and G.B. eliminators. Low cost of operation, minimum amount of attention, together with reliability and safety, make a Met-Vick Hospital Set, an ideal installation for any institution.

'Chorda' Catgut

After extensive experimental work in the London Hospital, 'Chorda' Catgut has been evolved. This catgut is sterilized by a special iodine process which obviates the disadvantages hitherto associated with iodine sterilization.

Thus, while ensuring complete sterility, the tensile strength of the ligature is not impaired. Most of the iodine being finally removed in the process no irritation is produced by the ligature in the tissues.

Prepared in all sizes from 6/0 to 6 in both plain and hardened.

5/- per box of 3; 18/- per box of 12 tubes. When ordering please specify '*Chorda*' *Catgut.*

BRAND'S ESSENCE OF BEEF for INVALIDS

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN

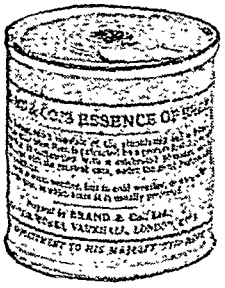
contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

Sold by Chemists Everywhere.

Prepared by

BRAND AND COMPANY LTD.

LONDON, S.W.8.



OVALTINE

AN EFFICIENT GALACTAGOGUE.

In addition to its value as a means of promoting the nutritional welfare of the mother and child, clinical experience extending over many years has conclusively shown that "Ovaltine" has specific galactagogue properties. As a result of its administration, there almost invariably follows a marked improvement in the flow and quality of the milk.

The following is an example of many reports received:

"In more than one case I have found 'Ovaltine' bring back the milk supply after everything else had been tried. In one case I discontinued the use of 'Ovaltine' after the desired result had been obtained, but I found at the same time the milk supply also diminished, necessitating the resumption of the use of 'Ovaltine.'"

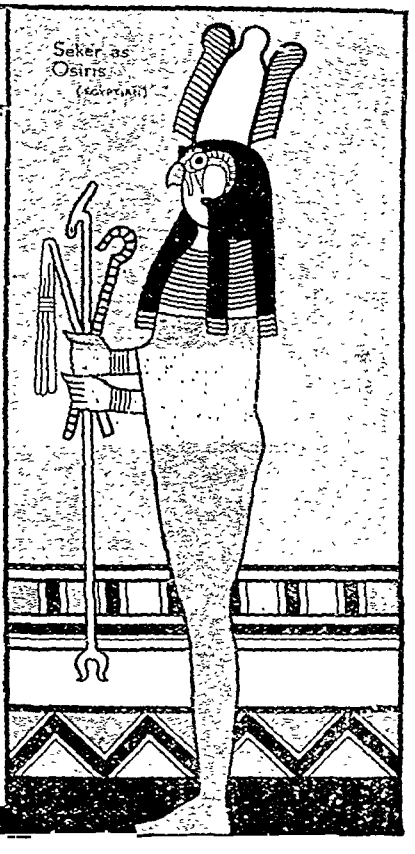
To ensure adequacy of the milk supply many physicians order the use of "Ovaltine" to commence during the eighth month of gestation and to be continued throughout the nursing period. In this way the mother is not only enabled to withstand the extra strain which the childbirth throws upon the system, but to nurse her child from the outset in the best possible way. "Ovaltine" is delicious as well as highly nutritious, and involves no troublesome preparation.

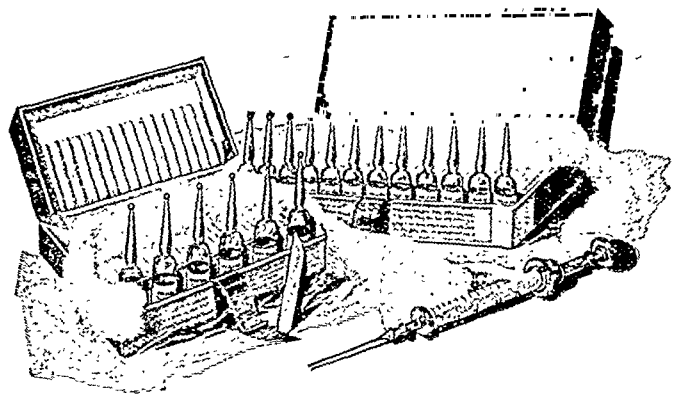
A liberal supply for clinical treatment sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W. 7.

Works: KING'S LANGLEY, HERTS.

M. 206





Manganese Butyrate

B. D. H.

Case 1.—"Staphylococcic infection multiple boils all over. Cleared up entirely on Manganese Butyrate."

Case 2.—"A patient suffered from vaccination erysipelas for four days, having a temperature of over 104°. On the day following an injection of 1 c.c. of Manganese Butyrate, the swelling and redness of the extremity had vanished and the temperature had become normal."

From the clinical reports cited above it is obvious that Manganese Butyrate B.D.H. is a drug of considerable value. Acute staphylococcic and streptococcic infections respond particularly well to Manganese Butyrate therapy.

Manganese Butyrate B.D.H. is issued in ampoules and in rubber-capped vaccine bottles containing a solution ready for intramuscular injection.

INFANT FEEDING

a common problem for every Doctor

THE countless reports we receive show that much trouble would have been saved to the medical man and patient if Humanised Trufood had been his first choice in selecting an infant food. Many doctors write to tell us of the trouble they have been saved by making a simple practice of always advising Humanised Trufood as the first choice for all cases of infant feeding.

A case reported:—

"*Mother aged 17, Baby Boy born after 28th week of pregnancy.*

The breast milk was drawn off and given with a pipette, but owing to the Mother's condition other feeding had to be substituted. Cow's milk, 10 minims to the drachm, produced green stools—convulsions also occurred.

Your sample of Humanised Trufood was tried with immediate success and the infant is progressing favourably, is quite contented, stools normal—sleeps perfectly, only waking for feeds."

The proof that Humanised Trufood is definitely *nearest to mother's milk* has been established by independent tests recently carried out by one of the best known Laboratories in the country.

Documentary evidence and samples promptly sent on request.

HUMANISED

TRUFOOD

TRUFOOD, LTD., THE CREAMERIES, WRENBURY, NR. NANTWICH, CHESHIRE.

High Blood Pressure

(Hyperpiesia)

A Man is as Old as his Arteries

Postulate 1.

Let it be granted that the intestine daily contains large quantities of toxic substances from the decomposition of food by bacteria.

Postulate 2.

Let it be granted that the absorption of these toxins must result in *diminished resistance*, or loss of control of the natural defences of the tissues generally and the circulatory system in particular.

Postulate 3.

Let it be granted that these toxins present in the blood are conducive to all the symptoms and signs associated with high blood pressure.

Then it can be demonstrated that *treatment for permanent improvement* of persons suffering from high blood pressure must include some form of daily intestinal disinfection to control the manufacture of 'pressor' toxins.

Q. E. D.

Dimol does this effectively*

It has a Rideal-Walker Co-efficient of 35.

It is absolutely non-toxic and does not find its way into the circulation.

It can be given over prolonged periods without any deleterious effects on the intestinal mucosa.

**Clinical evidence will be sent to any Medical Practitioner on application to the*

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. Nujol readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis, frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of constipation.

'ZYMINE' Peptonising Tubes

(FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick.

'Zymine' Peptonising Tubes have been in use since 1882, making it possible for physicians to assure proper nutrition to their patients, even in cases where digestive power has been reduced to its lowest terms, and enabling chronic dyspeptics, invalids, convalescents, etc., who must live upon fluid foods for more or less prolonged periods, to take milk in quantities sufficient to maintain nutrition and promote restoration.

Peptonised milk presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk an available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomp'ishes the desired purpose.

Supplied in boxes containing 6 and 12 Tubes.

The contents of one Tube will peptonise one pint of milk.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK, and 65, Holborn Viaduct, LONDON, E.C.1.

English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURES.

Typical Case.

F. D. A., female, aged 12 years.

Diagnosis: Fracture of femur, malunion, malposition.

Operation: Reduction with Gratton osteoclast seven weeks after injury.

Anæsthesia: Local infiltration block 7 cm. above the point of fracture. 90 c.c. of 0.5 per cent. Novocain-Adrenaline solution were used. The child's limb was small, and therefore but a moderate amount of solution was required. The thigh was heavily padded with felt, and the Gratton instrument applied. The bone was refractured and the result checked up by roentgenograms before the removal of the Gratton instrument. This child had no pain at the point of fracture, but complained moderately of the stretching of the muscles, which gave some distress in the region of the knee-joint. However, the anæsthesia was entirely satisfactory, and the child partook of a hearty meal while the plaster cast was being trimmed.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full particulars of this and one hundred other operations under Local Anæsthesia will be found in above work, published by Henry Kimpton, 263, High Holborn, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine

Sparkling Pine Bath Tablets

for nervous & heart disorders, rheumatic conditions, etc., etc.

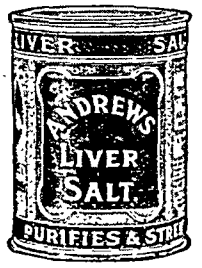
Constipation

In spite of dietetic measures and exercise many patients still suffer from the devitalising effects consequent upon intestinal stasis. To such, the attainment of perfect health is debarred. Whether in disease or convalescence faecal stagnation retards recovery.

In health and in the majority of pathological conditions, an efficient and safe aperient will be found in Andrews Liver Salt. It is a briskly effervescent Saline with a pleasant taste.

Antacid in action, it stimulates the secretion of bile and of the mucus glands of the intestines, and causes a semi-fluid stool and a painless, easy evacuation.

Especially indicated in the constipation of childhood and old age; of inestimable value to those who travel; and a valuable adjunct in the treatment of those conditions incident to hepatic congestion and torpidity.



Dose ½ - 3 teaspoonfuls (according to requirements) in a glass of water.

An 8-oz. Tin sent free on request.

Andrews Liver Salt

SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T. M. & Design).

In Original Boxes of 12 "Sterules."

Price 3/=

Containing 1, 2, 3, 4, 5, 6 or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.35 or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving Angina Pectoris, Spasmodic Asthma, Migraine, Post-Partum Hæmorrhage, Hæmoptysis, Sea Sickness, to ward off Epileptic Attacks, &c., and as an Antidote to Chloroform.

Largely employed in threatened Fainting and Collapse, and as a restorative after Gas in Dental Operations.

"In ANGINA PECTORIS the best remedy. An early recognition of excessive tension is an important step towards longevity. To lower blood pressure Amyl Nitrite has a more rapid action than any other drugs, and is useful in cutting short the paroxysms of pain. Nitroglycerin in divided doses keeps the tension low during the day. Nitro-Erythrol has a lower and perhaps more prolonged action."—L., ii./05, 325; ii./06, 1335.

ANGINA PECTORIS GRAVIOR. The more pronounced attacks were treated with Amyl Nitrite and Nitroglycerin, which gave prompt relief.—B.M.J., ii./06, 304.

In all spasmodic affections, such as Angina pectoris, one of the best remedies.—B.M.J., i./09, 994.

Discussion on angina pectoris—"The Nitrites are indispensable."—B.M.J., ii./09, 1122.

When the pain is acute Amyl Nitrite the quickest means of relieving.—L., ii./08, 1132.

Fear of death entirely disappeared as patient knew he could get relief from Amyl Nitrite or Nitroglycerin.—L., ii./09, 572.

In angina no drug can compare with Amyl Nitrite for immediate action and efficiency.—L., i./09, 240; L., ii./05, 812.

INTRATHORACIC ANEURISM. For the acute anginal attacks—Amyl Nitrite inhalation followed by internal use of Nitroglycerin or Erythrol Nitrate ½ or ¼ grain is generally efficacious.—L., i./13, 948.

In ASTHMA in most cases the reduction in blood pressure relieves.—B.M.J., ii./11, 1327.

POST-PARTUM HÆMORRHAGE immediately stopped; no further trouble followed.—B.M.J., ii./06, 1125.

HÆMOPTYSIS in pulmonary tuberculosis, 90 cases treated by immediate use of Amyl Nitrite, and with few exceptions promptly effective. *Possession of the remedy secures peace of mind to sufferers.*—L., i./08, 130.

Some convincing cases in which AMYL NITRITE SAVED LIFE.—L., i./07, 939.

In hæmoptysis, the general widespread vaso-dilation produced by Amyl Nitrite is preferable to the vaso-constriction effected by adrenaline internally.—L., ii./04, 1446.

In hæmoptysis Amyl Nitrite acts better the quicker it is used. In most cases it can be completely arrested if inhaled as soon as the first signs of blood show themselves in the sputum. If excitement afterwards of any kind, ¼ grain Morphine given. Amyl Nitrite, the drug *par excellence*, to be used first. Especially useful in sanatorium work where the patient is seen at the beginning of attack.

Hæmoptysis arrested in every case in which Amyl Nitrite was tried whether of mitral obstruction or from phthisis.—Edin. Med. J., July, 1904; L., ii./04, 522, 942, 1446; M.A., 1906, 240; B.M.J.E., i./06, 79. In severe hæmoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory.—B.M.J., i./06, 917.

In SEA-SICKNESS, inhalation from a "Sterule" is very useful; should be repeated every 2 or 3 hours if necessary.

In CHLOROFORM SYNCOPE Amyl Nitrite affords the quickest means of restoring the heart's action.

Infantile Convulsions well treated by 1 minim capsules.

Please specify MARTINDALE'S Amyl Nitrite "Sterules"—the Original Manufacturer.

We also Supply:

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British wholewheat crispbread, in place of soft wholemeal or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric, and Protein content.

It is an all-British crispbread, guaranteed to be made from 100 per cent. stone-ground whole-wheat grown within the Empire. It is of distinctive texture, inviting mastication and insalivation; it has a delicious "crunchiness" and a pleasing ripe-corn flavour; and it contains every part of the wheat berry, nothing whatever being removed in the process of manufacture.

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation.

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

Vitamins

AND DRIED MILK

The vital importance of an adequate supply of vitamins in the feeding of infants is now well recognised, not only in the prevention of obvious deficiency diseases such as rickets and scurvy, but also in the maintenance of the general resistance against the common infections of the respiratory, alimentary, and urinary tracts, and the determination of a normal equilibrium between the various endocrine secretions.

Cow & Gate Milk Food

The vitamin content of milk depends in the first instance on the character of the diet supplied to the cows. English pasture-fed herds furnish a milk superior in its vitamin content to that of stall-fed animals or those fed on inferior pastures of dry and tropical climes. The Cow & Gate dairy farms and laboratories are situated in the rich pastures of Somerset and Dorset, and thus a high vitamin content of their milk is assured, obviating the necessity for the addition of synthetic vitamin concentrates which are very doubtful in their action.

The survival of the vitamins in the dried product depends on the process employed. The Cow & Gate Roller process of drying milk involves exposure to heat for a matter of seconds only, with the result that the vitamins are for all practical purposes intact.

There have been no proved cases of rickets where Cow & Gate Milk Food has been used. Many feeding experiments in the hands of well-known investigators have demonstrated that adequate nutrition and growth are assured on a diet of this food, which has now been widely recommended by the Medical Profession for over a quarter of a century.

The Manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

GENOVAX

A new local detoxicated vaccine for the treatment of Pyorrhoea

Researches in Local Immunity have shown that by the application of dead bacteria a powerful immunity can be produced in the skin and mucous membranes. Working on this discovery several investigators have found that excellent results are obtained in the treatment of pyorrhœa by injecting small quantities of a pyorrhœa vaccine immediately under the mucous membrane above or below the affected gums. While an ordinary vaccine produced a painful inflammatory reaction, the detoxicated vaccine was injected in much larger doses without any subsequent painful effects.

A Dental Surgeon reporting on the results obtained by the use of a detoxicated pyorrhœa vaccine prepared in a London hospital and now available to the profession under the name of Genovax, wrote in the *British Medical Journal.*

"I notice that the first injection has a tonic action on the patient, and as the course—which generally consists of ten treatments—progresses the general health steadily improves. Foul odour and bad taste in the mouth disappear, the pus decreases, the gums become more firm, and the teeth tighten. I have even noticed that roots discharging the pus characteristic of chronic alveolar abcess dry up, so to speak, and after extraction their sacs appear to be shrivelled and inert. There are, however, some cases too advanced for any cure except that of extraction; for example, if pyorrhœa involves as much as one-third of the membrane from the apex, the remaining part of the periodontium of the tooth, being necrosed, cannot be brought to life again, so the tooth involved can never be tightened up sufficiently to be useful for mastication, and the best treatment would then be extraction. Even in such cases, however, a course of vaccine given before extraction is followed by much more rapid healing of the tissues after the operation and by less systemic disturbance. The treatment, used before the operation, acts preventively also where infection is expected to follow surgical action.

Such results justify the hope that in the future pyorrhœa alveolaris will prove to be always curable, and that this treatment will serve as a prophylactic against toxaemia and systemic complications of pyorrhœa."

A description of the researches which led to the introduction of Genovax and particulars of treatment and prices are given in the first Genatosan Dental Bulletin, a copy of which will be sent to any practitioner who applies to

LEAF FROM A MANUSCRIPT IN WHICH HAVE BEEN PRESERVED EARLY INDIAN MEDICAL COMPOSITIONS.—In the introduction the writer states that the book contains the wisdom of many "sages of enlightened mind." The folio here reproduced reads: ". . . . Health, plumpness, spirits, energy and long life, all are dependent on the digestive faculty. The digestive faculty is set in activity through food; and the resultants of digestion are the elements; health depends on the normal condition of the elements; plumpness on health; good spirits and energy on plumpness; and through all these the life of living beings is prolonged . . . . When the digestion is weak one should fast at first and afterwards use medicines to promote appetite and assist digestion; the use of liquors medicated with powders is advantageous in removing derangements of the bile and phlegm. When the digestion is weak or too active, a person dies, unless he receives proper treatment; when it is irregular, he contracts all sorts of diseases; when it is regular, he lives long in comfort. Hence a wise physician will first direct his treatment to the proper regulation of the digestive faculty, afterwards paying attention to the relief of the sickness. He who desires a good memory, health and strength, and wishes for a long life, should make use of the fresh juice of the Saṅkhapushpī (Canscora decussata), Brāhmī Mandūkaparnī (Hydrocotyle asiatica) and liquorice."

VITAMINS A, B & D

HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession — a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

THE IDEAL SEDATIVE

ELIXIR BROMO-VALERIANATE GABAIL

IN ALL NERVOUS AFFECTIONS

A useful combination of Deodorised Valerianate with Strontium Bromide which advantageously replaces all other forms of Valerian and Bromide in the treatment of functional nervous disorders,

HYSTERIA, NEURASTHENIA, PSYCHASTHENIA, INSOMNIA.

Also valuable in states of temporary emotional or mental excitement, in Hypochondriasis and Melancholia.

Agreeable in flavour and taste, the odour of Valerian being not merely disguised but completely removed.

To ensure your patients receiving this original preparation prescribe

Remarks
ON
THE GALL-BLADDER IN RELATION TO FOCAL INFECTION.*

BY
D. P. D. WILKIE, M.Ch., F.R.C.S.,
PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH.

GALL-BLADDER disease commands our attention from three aspects—namely: (1) As a cause of recurrent attacks of acute abdominal pain. (2) As a cause of persistent reflex flatulent dyspepsia. (3) As a focus from which infection spreads to various organs and tissues throughout the body.

With biliary colic and with gall-bladder dyspepsia we are all thoroughly familiar, and I do not propose to touch on these subjects, nor will I refer to complications such as obstructive jaundice and pancreatitis. Our concern to-day will be entirely with the infective aspect of gall-bladder disease and its relation to certain common ailments of obscure etiology.

The importance of the study of the "pathology of the living," which Moynihan has done so much to emphasize, is seen nowhere to such advantage as in the investigation of biliary disease. Post-mortem pathology taught us practically nothing in regard to the essential features of infection of the biliary passages. The gall-bladder is the organ above all others which suffers from early post-mortem changes which mask all the finer pathological features. Indeed, the frequency with which gall-stones were found at post-mortem examination tended to obscure the significance of gall-bladder disease and its relation to other morbid changes

To surgery belongs the credit of disclosing the frequency of gall-bladder infection and of defining its essential characters. The study of the early stages of cholecystitis in the operating theatre and clinical laboratory has proved a fruitful field of observation during recent years, and the correlation of this study with experimental research has led to results which are fundamental in their bearing on pathology. The practice of extirpating the gall-bladder when it has shown clear evidence of disease has provided an experiment the results of which have been illuminating, and we are now in a position to speak with some assurance regarding the role which this organ plays as a seat of focal infection. We now know that gall-bladder infection, far from being merely the result of the straying of bacteria into its lumen by way of the bile, as was so long believed and taught, is a very definite specific blood-borne infection of the wall of the organ by a streptococcus which has a specific affinity for this tissue. This idea, which sprang from the pioneer work of Rosenow, has received ample confirmation in the Surgical Research Laboratory in Edinburgh, from the work of Illingworth, and of A. L. Wilkie. The latter was able to isolate a streptococcus from 84 out of 100 gall-bladders removed at operation for biliary disease. He showed that, whilst the bile was usually sterile, there could be isolated from the wall of the viscus, and still more readily from the cystic lymph gland, a streptococcus which had this peculiarity—that it was killed or its growth inhibited by the presence of bile. The customary method of making cultures from a snipping of the whole thickness of the gall-bladder wall had failed to obtain a growth because the mucous membrane, included in the section, had bile adhering to it.

Wilkie showed that intravenous injections of an emulsion of this streptococcus into rabbits produced with great regularity a chronic cholecystitis with gall-stone formation in every way similar to that found in the human subject. The *Streptococcus viridans*, which was isolated in these cases, resembled closely that found so frequently in pyorrhœa, in infected dead teeth, in chronic tonsillitis, in chronic gastric ulcer, in chronic appendicitis, and in the nodules in chronic muscular rheumatism. In a few cases, three or four in all, we have isolated *B. welchii* from the wall of the gall-bladder, and, although rare, this form of infection is peculiarly toxic, and in its acute phase may prove fatal. The *B. coli*, although not infrequently found in acute obstructive cholecystitis, has proved in our experience to be a rare type of infection in chronic gall-bladder disease.

The conception of chronic cholecystitis as a blood-borne streptococcal infection situated within the wall of the gall-bladder, indolent, slow, tenacious, causing at first little interference with the bile storage and concentrating functions of the organ, but permitting of streptococcal invasion of the lymph stream, as evidenced by the frequent presence of the organism in the cystic lymph gland and thence possibly infection of the blood stream—this conception, now a proven reality, establishes the important role which the gall-bladder may play as a focus of infection. There is now a considerable body of proof that a chronic streptococcal infection may have an intimate etiological relationship to many of the so-called chronic rheumatic conditions of joints and of fascial planes, to myocardial degeneration, to certain renal conditions, and to some affections of the central nervous system.

Possessed of the knowledge that the gall-bladder is very frequently the seat of a chronic streptococcal infection, it would seem to be only natural that we should search for evidence of gall-bladder disease when casting about for a focus of infection in our investigation of cases of any of the above-mentioned maladies. I propose to refer to some cases in which such an etiological relationship appeared to be possible and in which the removal of an infected gall-bladder was followed by a notable amelioration in the secondary lesion.

Chronic Arthritis.

Miss S., aged 32, had suffered for almost two years from a chronic rheumatic affection of both knees which did not yield to local treatment or anti-rheumatic remedies, and which incapacitated her from all forms of active exercise. She also suffered from a mild flatulent dyspepsia, and on two occasions during the past six months had had an attack of severe pain in the upper abdomen, accompanied by vomiting and diarrhœa, and by marked tenderness under the right costal margin.

On examination she looked healthy and was well nourished. Her knees were slightly swollen and were painful on movement. Definite tenderness was elicited over the gall-bladder. A cholecystogram showed a fairly well-defined gall-bladder shadow.

At operation, in January, 1928, the gall-bladder was found to be small, was slightly opaque, but not appreciably thickened. There were no gall-stones; the other abdominal organs showed no abnormality. The gall-bladder was removed and cultures were taken from the bile, from the gall-bladder wall, and from the cystic lymph gland. Those from the bile and gland were negative, that from the wall of the gall-bladder gave a pure growth of a streptococcus which, on injection into rabbits, produced cholecystitis.

Progress.—One year after operation the patient reported that within a few months of the operation the rheumatic condition of the knees had cleared up completely, and that she could skate and play badminton for hours on end without ill effect.

Comment.—The above case is one of a number in which so-called rheumatoid joint conditions have shown lasting improvement following cholecystectomy.

Toxic Myocarditis.

Mrs. A., aged 45, complained that for two and a half years she had suffered from increasing breathlessness and palpitation on slight exertion. She had been subject to persistent flatulence after meals for at least seven years, and on several occasions had been laid up with attacks of severe pain in the epigastric region and the right side of the chest, and had been treated for "congestion of the lungs" in two of these attacks. Owing to her inability to take exercise without distressing breathlessness she had got much stouter during the past year.

On examination the patient was rather stout, pale, and of poor muscular tone. Moderate exercise induced breathlessness and rapid heart action. There were no cardiac murmurs, but the heart sounds were feeble. There was very definite tenderness on pressure below the right costal margin. A cholecystogram showed a definite gall-bladder shadow with a few negative areas indicating calculi.

A diagnosis of cholecystitis with gall-stones and myocarditis was made and operation was recommended.

Operation (June, 1926).—Owing to the heart condition gas and oxygen and ether were chosen as anæsthetics. A greatly thickened gall-bladder, containing numerous calculi, was removed. A pure growth of a streptococcus was obtained from the wall of the gall-bladder; the bile was sterile. Apart from having a rapid pulse rate for several days following operation the patient made a

* Part of an address (with lantern demonstration) to the South Wales and Monmouthshire Branch at Porthcawl on May 16th, 1929.

satisfactory recovery, and on leaving hospital was instructed to take graduated exercises.

Progress.—Two and a half years later the patient reported, looking thinner, with a healthy complexion, and obviously in good physical condition. She stated that during the year following the operation she gradually increased her physical exercise and was now able to walk and to climb stairs without any of her former distress.

Comment.—The "cholecystitic heart," as it has been termed, is, in my experience, a very common condition. It would appear to result from chronic toxaemia, probably first a slight myocardial degeneration, later complicated by fatty infiltration owing to the patient's inability to take exercise without distress, and the consequent obesity so common in these cases. It is the myocardial change which presents the chief risk of operation in old-standing and neglected cases, and which makes acute infective complications, when they supervene, so dangerous.

Toxic Nephritis.

The following case, although standing by itself, was perhaps the most dramatic in the series, and the credit for the successful result rests with the physician who advised, rather than with the surgeon who, with considerable trepidation, carried out the operation.

Mrs. B., aged 63, had for some years suffered from a chronic flatulent dyspepsia. In August, 1927, she had an acute attack of obstructive cholecystitis with great pain and fever, associated with a large palpable gall-bladder. As this was subsiding she developed the signs of nephritis—namely, marked generalized oedema and urine loaded with albumin. This persisted week after week and had several distinctive features. The oedema would vary greatly, even in the course of one day. As a rule there was a state of complete generalized anasarca, the conjunctivae hanging out as oedematous sacs. Twenty-four hours later, without apparent reason, the oedema would be much less. The excretion of urea was normal, as was the blood urea. There were no retinal changes. It was thought that the nephritis, or perhaps more accurately the nephrosis, must be toxic in origin and the diseased gall-bladder the most likely focus.

When first seen by me in October, 1927, the patient showed complete anasarca, the abdominal wall was oedematous, the abdomen contained much free fluid, and the limbs were tense and shiny with oedema. The risk of operative intervention appeared to me to be unjustified, and an expectant attitude was advised. The renal condition, however, showed no signs of improvement, and on November 21st, 1927, operation was undertaken.

Operation.—Twilight sleep and local anaesthesia, supplemented by gas and oxygen, was used. A Kocher incision was made through the extremely oedematous abdominal wall. A considerable quantity of free fluid escaped from the abdomen on opening the peritoneum. A very large, inflamed, and greatly thickened gall-bladder was exposed and tapped, muco-pus being drawn off. The gall-bladder, which contained one stone blocking the neck, was removed. Owing to the great oedema of the retroperitoneal tissues palpation of the kidneys was impossible. From the cystic gland a pure growth of *Streptococcus viridans* was obtained, and emulsion of this injected into a rabbit produced typical cholecystitis. Cultures from the muco-purulent content of the gall-bladder gave no growth.

Progress.—The patient was upset but little by the operation; within a week the oedema was seen to be disappearing rapidly and the albumin in the urine was diminishing. At the end of a month all oedema had gone and but a trace of albumin remained. Three months after operation the patient had resumed her normal life, and now, eighteen months after, she is enjoying better health than for many years past.

Comment.—This most striking case of immediate recovery in a waterlogged patient on removal of an infected gall-bladder confirmed our opinion that focal infection in this viscus has wide clinical bearings.

Toxic Hepatic Cirrhosis.

It has been held by many that an infective hepatitis may be the precursor of cholecystitis, the gall-bladder being infected through the lymphatics which reach it from the liver. The experiments of A. L. Wilkie showed that this is probably not the case. On the other hand, an infected gall-bladder usually leads to a local hepatitis, and may, as in the following case, have an etiological bearing in a true general hepatic cirrhosis.

Mr. A., aged 62, complained of flatulent dyspepsia, occasional attacks of dull pain in the region of the liver, of lassitude, loss of energy, and shortness of breath. He was not a heavy drinker, but had taken alcohol in strict moderation.

On examination he was seen to be of a high colour with a slightly cyanotic tint. The conjunctivae showed a definite icteric tinge. The liver was enlarged, its lower border being readily palpable one and a half inches below the right costal margin. There was very definite tenderness localized over the gall-bladder region. There was no free fluid in the abdomen and no swelling of the legs. A diagnosis of chronic cholecystitis was made, but operation was deemed to involve a risk in view of the cyanosis and hepatic enlargement. Persistence of pain and tenderness in the gall-bladder region, however, led ultimately to a decision in favour of operation.

Operation (June 6th, 1927).—On opening the abdomen the liver was seen to show the typical appearance of a hypertrophic cirrhosis involving the whole organ. The gall-bladder was not enlarged, but was greatly thickened, evidently from long-standing chronic inflammation. There were no gall-stones. The gall-bladder was removed, and from its wall and the cystic gland a pure culture of streptococcus was obtained.

Progress.—The immediate recovery was uneventful, but a guarded prognosis was given. One year later the patient reported, looking extremely well, with a fresh complexion and no trace of cyanosis. He stated that he had now no dyspepsia, was able to take active exercise, and was never breathless. On examination his liver was not palpable.

Comment.—Whilst this case is, in my experience, quite exceptional, it serves to show that the infection of the gall-bladder may occasionally be the determining cause of hepatic cirrhosis.

Toxic Mental Derangement.

The following case, for the notes of which I am indebted to Mr. J. J. M. Shaw, under whose care the patient was, illustrates the part which cholecystitis may play in relation to some forms of insanity.

J. C., aged 44, wounded in 1916 and taken prisoner. Gas gangrene developed in a flesh wound of the thigh and the patient became insane. He was kept in an asylum for nine months, and it was noted that his insanity returned at the same time as his thigh wound finally healed. He enjoyed good health from 1917 to 1928, when he began to be troubled with symptoms diagnosed as those of mild cholecystitis. In October, 1928, he had an acute attack of cholecystitis with definite tenderness over the gall-bladder and faint jaundice. The day following the onset of acute symptoms he was admitted to a nursing home and the same evening developed acute confusional insanity with a marked tendency to violence, necessitating his removal to an asylum. One month later his mental state was one of complete mental confusion with inability to recognize his relatives.

On examination, under light anaesthesia, a resistance could be felt in the gall-bladder region.

The diagnosis of the alienist was "confusional insanity probably from a toxic focus."

Operation (November 19th, 1928, by Mr. Shaw).—A moderately distended and much thickened gall-bladder, containing one stone impacted in Hartmann's pouch, was removed.

Bacteriological examination of the gall-bladder gave a growth of a large Gram-positive bacillus. Unfortunately this was regarded as a contamination and the cultures were not preserved.

Progress.—After a few days of marked improvement in the patient's mental condition there was a period of three months during which it remained uncertain. This was followed by steady improvement, and he was discharged from the asylum four months after the operation and returned to work. He is now, six months after operation, able to transact legal business without effort.

Comment.—The onset of insanity in this case with the development of gas gangrene in his war wound; the return to sanity coincidentally with the healing of the wound; the later attack of insanity along with the development of an acute cholecystitis; the regain of sanity following the removal of the inflamed gall-bladder, from the wall of which a Gram-positive bacillus was grown—these facts all point to an intimate relationship between the focus of infection and the mental derangement.

The cases recorded above have been selected as offering striking evidence of the importance of intramural infection of the gall-bladder in relation to certain chronic ailments. It is not suggested that in these diseases the gall-bladder will always be found at fault, but it is claimed that biliary infection has more than a local significance, and that it is the infection in the wall of the organ, and not its content, be that bile, pus, or calculi, which is the essential factor in its pathology.

"VIRGIN SOIL"—AND AFTER.

A WORKING CONCEPTION OF TUBERCULOSIS IN CHILDREN, ADOLESCENTS, AND ABORIGINES.

BY

S. LYLE CUMMINS, C.B., C.M.G., M.D.,

DAVID DAVIES PROFESSOR OF TUBERCULOSIS, WALES.

THE expression "virgin soil" in connexion with tuberculosis is generally used to describe the unprotected state of persons belonging to isolated communities so far cut off from human agglomerations as to have escaped all effective contact with the tubercle bacillus. The marked susceptibility of such persons when exposed to infection is generally admitted, and is quite similar to the susceptibility of wild animals when first domesticated or brought into confinement. For the medical practitioner in this country, however, the real interest of this great susceptibility of "virgin soil" to tuberculosis lies in its bearing upon the tuberculosis of infancy, childhood, and adolescence; and it is the importance of this aspect of the question that constrains me to submit a few general reflections on the subject.

The tuberculosis of early life differs in certain important respects from the tuberculosis of later life; and, great as has been the fall in tuberculosis at all age groups, coincident with the rise in the general standards of living within the last fifty years, these differences do not tend to disappear. In infancy and early childhood those individuals—happily much less numerous than formerly—who develop tuberculous disease still do so in three main forms: "primary foci" at portals of entry; adenitis of the cervical, mesenteric, and tracheo-bronchial glands; and, where the initial infection has been heavy or circumstances unfavourable, in the form of a generalized infection manifesting itself as disseminated tuberculosis, caseous pneumonia, or tuberculous meningitis. These three main types are matched by similar manifestations in the tuberculosis of "primitive" adults brought into contact with infection for the first time, and are comparable with the experimental tuberculosis produced in laboratory animals. They represent what I have ventured to call "natural" as opposed to "modified" tuberculosis.

As will be readily seen from the types above enumerated as characteristic of "virgin soil," tuberculosis, even in its "natural" phases, presents marked contrasts in severity, depending not merely on differences in natural resistance, but to a very large extent upon variations in the numbers of bacilli involved, the frequency of repetition of infection, the hazards of anatomical localization, and the time factor or incubation period intervening between the entry of the bacilli and their multiplication to numbers sufficient to produce disease. And, in view of the gradual and steady rise in the percentage of positive tuberculin reactions in the apparently healthy as the children grow older, we are in a position to know that, in the vast majority of instances, infection may occur, even at these susceptible ages, without passing on into disease. This is a point on which stress must be laid. Many appear to believe that tuberculous infection in virgin soil invariably causes acute and progressive tuberculosis. Nothing could be more untrue. All of us were once virgin soil to the tubercle bacillus, no matter how high our resistance may have since become. The fact is that in all except those cases in which the initial dose has been large, the process of "modification" starts at once and proceeds *pari passu* with the infective process, the resistance outstripping the disease or lagging behind it according to circumstances, so that the tissues soon cease to be virgin soil. The characteristic of tuberculosis in virgin soil is not necessarily a high morbidity, but a high case mortality. Latent infection tends to be well tolerated, but the *disease*, when it occurs at this stage, is usually severe.

Perhaps the most interesting age period in relation to tuberculosis is that which follows infancy and early childhood and leads on towards puberty. This age period may *appear* from a study of tuberculosis mortalities in the Registrar-General's reports to be one at which the resistance is high and the liability to tuberculosis minimal. It is undoubtedly a period in which the tendency to the infantile or fulminating type of tuberculosis has for the most part disappeared, and in which the tendency to the adult form of apical phthisis has not yet become marked. That is why it is the period of lowest tuberculosis mortality. But, from the point of view of the student of tuberculosis, it is a "larval" period, during which the fate of the individual is often in the balance, a period so little understood and so full of unsolved problems that it can hardly be discussed without raising controversial questions. This "larval" period, though characterized by a low mortality, has a fairly high and a fairly characteristic morbidity, depending upon the gradual fruition of successfully localized but not successfully arrested "infantile" lesions, and appearing in such forms as cervical adenitis, hip-joint disease, spinal caries, and all the various affections of bones, joints, and lymphatic glands; tuberculous conditions which cause a great deal of suffering and deformity, make prolonged claims on bed accommodation, but do not, as a rule, lead to a fatal issue. These lesions of the "larval" period are, in fact, found to be consistent with an astonishing absence of constitutional disturbance if the patient, and the affected part, be kept at rest and "secondary" infections prevented. A glance round the "surgical tuberculosis" wards at Alton or Llangwyfan will convince the observer that advanced tuberculosis of bones and joints, if properly managed, is quite consistent with rosy cheeks, well-nourished limbs, and a fine state of general health.

It is not suggested that the whole of this period of childhood and adolescence is consistently the same in relation to tuberculosis. The earlier the age, the closer the assimilation to the "generalized" tuberculosis of infancy; the later, the more marked the tendency to "adult" pulmonary types. On the whole, however, childhood and adolescence is the period of non-pulmonary localization combined with a surprising degree of "tolerance" to the disease.

Now if the visible and easily detected manifestations are so well tolerated at this stage, it is not difficult to realize that invisible and hidden lesions may go completely unrecognized. Suppose, for instance, that the neck were as safely concealed from view as the roots of the lungs and the mediastinum, how often would cervical adenitis escape our notice? It is this very quality of "tolerance" to tuberculous lesions that stamps this "larval" period with its peculiar importance and its characteristic dangers. For the hidden dangers of this period are just as characteristic as its "tolerance," and are best appreciated in terms of the latter.

We may assume that, so far as milk-borne bovine tubercle bacilli are concerned, the primary lesions are, for the most part, easily detected, being situated in the cervical or the mesenteric lymph nodes, which receive the lymph drainage from portals of entry in the tonsillar and pharyngeal regions and the intestinal tract. The difficulties of detection are much greater, however, in the case of infections with human tubercle bacilli, which, being for the most part breathed into the lungs with the inspired air, set up minute "primary" focal lesions—usually only recognized, at this stage, at post-mortem examinations, but actually very common—from which the bacilli pass on to cause far larger and more important lesions in the tracheo-bronchial glands.

The preponderating importance of these insidious thoracic lesions in initiating generalized tuberculosis is shown by the fact that A. Stanley Griffith has found human tubercle bacilli in 73 per cent. of cases of tuberculous meningitis. We learn, too, from the combined pathological and radiological observations of Opie, that, at a later stage, when the primary lung lesions have become calcified and reached a stage of good *x*-ray visibility, a large percentage of adult lungs show evidence of having been infected with "primary foci" in childhood. It is probable that many enlarged tracheo-bronchial glands escape detection in *x*-ray films through being too small to project visibly into the lung fields or through being obscured by neighbouring structures, nor is it possible to say that a glandular enlargement seen in an *x*-ray picture is necessarily tuberculous;

but the combined evidence of radiology and post-mortem pathology points strongly to the conclusion that many apparently healthy children and adolescents have latent tuberculosis in the tracheo-bronchial glands.

Now the sinister aspect of these latent lesions of hidden glands lies in the fact that, during the period of childhood and adolescence, they continue to contain caseo-necrotic foci which may easily be awakened into dangerous activity or from which small infective emboli may enter the blood stream. It is one of the fortunate circumstances of human development that this age period is, in most cases, a time of life free from personal responsibility and admitting of plenty of open air and exercise followed by adequate rest. At no other time is life, on the whole, so healthy and natural as at school age. But if we look more closely into the question we find that the stresses of this age period are definitely associated with increased liability to the acute forms of tuberculosis. Inquiry into the case-histories of children suffering from "surgical" tuberculosis will very often elicit a history of injury as the determining cause of the disease. The very distribution of "surgical" lesions carries with it the same suggestion, tuberculosis being commonest in the structures most liable to stress and strain—the spine, the hip-joints, and the knee-joints. Again, in the case of the thoracic lesions of childhood, it is exceedingly common for these to have their onset determined by other respiratory infections, especially those causing congestion of lymphatic glands or causing thoracic strain through excessive coughing; examples being whooping-cough, influenza, and measles.

Turning to physiological stress, the earlier onset of puberty and sex character in the growing female is definitely associated with an earlier liability to tuberculosis than in the later-developing male. Even at the end of the adolescent period we find the same liability to break down under stress in the acute tuberculosis frequent in young males on entering strenuous industries—for example, coal-mining, an industry not otherwise characterized by any marked tendency to produce tuberculosis—and in the risks to young females after parturition and lactation.

And this leads me to the point which I wish specially to emphasize. We have clear evidence that, among healthy children and adolescents, just as among healthy adults, there is much latent tuberculosis. Tuberculin tests, radiological examinations, and post-mortem records prove this to be so. But within these groups of latent tuberculosis we ought to distinguish in our minds between the "larval" lesions of childhood and adolescence and the "compensated" lesions of later life. The former would appear to be far more liable to break down and cause autogenous reinfection than the latter. It is quite possible, on the other hand, that the "compensated" lesions, permitting of a gradual loss of immunity, may be consistent with a greater liability to exogenous re-infection; and the marked association of the pulmonary phthisis of middle age with certain industries suggests that this may be so; but this latter question is an intricate one requiring separate consideration.

It is interesting to note, in several recent observations on intradermal tuberculin tests in "healthy" persons, that among positive reactors there is a tendency for the end-point of reaction to graded dilutions to be higher in youth than in middle age, suggesting a greater degree of allergic hypersensibility: and yet we have reason to know that this state of hypersensibility of early age does not necessarily imply any very marked exemption from liability to tuberculosis under unfavourable conditions.

The sequence of events which suggests itself is, in my opinion, as follows: The "larval" stage, with its still unstable lesions, favours the auto-inoculations which lead on rapidly to a high degree of tissue allergy and, much more slowly, to a building up of the cellular proliferations and fibrotic barriers of spontaneous healing. During this "larval" period exposure to undue stress or to unfavourable physiological conditions is liable to produce such marked auto-inoculations as to lead on, not to increased immunity, but to secondary lesions and acute, often generalized, disease.

For those, however, whose lesions are smaller and better localized, or whose lives are exempt from undue stress, the danger period is gradually passed and the stage of "compensation" reached without breakdown. This, of course, is what appears to happen in the majority of cases in this country; and the resistance acquired in the process is sufficient to ensure the safety of nurses and doctors, and even of the majority of healthy partners of tuberculous husbands or wives, though exposed to many infective contacts.

Such reflections as these have assumed, for me, a new importance in connexion with the industrialization of African natives. The entry of South African natives into industry takes a different course from that which has been usual in these islands. Here, with the growth of our industrial centres which followed the application of machinery to production, the labouring man quitted his agricultural pursuits and transferred himself and his family to the towns, where he and his descendants had to adapt themselves as best they could to urban overcrowding and the bacterial "contacts" associated with it. The result has been a wide diffusion of tuberculous infection, and, after a period of high morbidity and mortality, a steady decline in both.

In South Africa, for the last thirty or forty years, the native labouring man has merely bidden a temporary farewell to his tribal home, and, leaving his dependants behind him, has sought the gold mines or other industries, not as a permanent resident, but for short "contract periods" of nine months or a year, during which sufficient money might be saved to enable him to rejoin the "leisured classes" in the Transkei or in Portuguese East Africa at the expiration of his contract. This system of alternate industrial stress and pastoral leisure has its advantages and its disadvantages. The good effects of hard muscular work combined with plenty of food are evident in the fact that the average native worker gains in weight and condition during his contract period and returns home a fitter as well as a wealthier man. But the system must inevitably lead, also, to the carrying home of the bacterial parasites acquired in industry and their diffusion among the kraals in the native territories. In these native territories, however, the mode of life is no more strenuous than that of the children of school age in this country, and contact with tuberculous infection, when not too intimate or intense, leads to much the same results. What has occurred has been, not a rapidly spreading epidemic of tuberculous disease in the kraals, but the gradual establishment of endemic tuberculosis, leading, in the sunny open-air life of a native population, to a high average of positive tuberculin reactions in "healthy" persons as well as to a fairly large number of relatively chronic cases such as might be found in a country town in Ireland, Scotland, or Wales. The more acute types do undoubtedly occur, but are not frequently seen because they die quickly, and, as likely as not, their deaths are attributed to hostile magic or some other malign influence.

In contemplating this widely diffused and relatively benign endemic tuberculosis the observer is tempted to exclaim, "But this is just like the tuberculosis we meet with at home." The real test, however, lies in comparing the behaviour of the "healthy but infected" adults from these native communities with the behaviour of similar groups of adults of European stock when exposed to the stresses of such an industry, for instance, as that of gold mining on the Rand. Under this ordeal we find that, in spite of the fact that about 80 per cent. of the native mine workers react positively to the intradermal tuberculin test on arrival at the mines, they exhibit a much more marked liability to tuberculosis than the young adult of Dutch or British ancestry in the same industry. And this liability is manifest not only in a higher morbidity and mortality, but in a marked tendency to revert to the generalized and progressive lesions usually regarded as characteristic of "virgin soil." It is obvious that, although arriving at the mines with a sufficient margin of health over infection to pass a stringent medical examination, these natives are in a far less stable condition in relation to tuberculosis than gold miners of European stock. In this liability to break down under stress they resemble the "healthy but infected" children and adolescents of this country, and their condition suggests that they are, for the

most part, in the "larval" rather than in the "compensated" phase of latent tuberculosis. This is a situation which is likely to reproduce itself in the more recently occupied parts of Africa as well as in other countries where hitherto isolated communities are being brought into increasing contact with European civilization. It would be well if industrialists in such countries studied the methods of prevention arrived at, through long experience, by the Johannesburg Chamber of Mines.

The importance of a correct appreciation of the factors underlying the phenomena of tuberculosis in "virgin soil—and after" is not, then, confined to the management of children and adolescents in this country, but has a wide bearing upon the future of industrial populations in our dominions, colonies, and dependencies.

I hope that the suggestions here set forth, but for which no originality is claimed, may serve to stimulate further thought and further investigation into some of the basic problems of our most formidable bacterial disease.

THE RADIATIONAL TREATMENT OF CORNEAL ULCERS.

BY

W. S. DUKE-ELDER, M.A., D.Sc., PH.D., M.D., F.R.C.S.,

ASSISTANT OPHTHALMIC SURGEON, ST. GEORGE'S HOSPITAL; ASSISTANT SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL.

In a previous paper in this *Journal*[1] a preliminary account was given of the application of ultra-violet light to ophthalmological diseases. Subsequent experience, extending to well over a thousand cases, has wholly confirmed the opinion then tentatively put forward; but the results of radiational treatment applied locally to ulcerative conditions of the cornea merit a separate and more detailed account.

The action of ultra-violet light is primarily abiotic—that is, destructive. The most obvious effect produced in the radiation of a cell is the photochemical denaturation and subsequent coagulation of its proteins. This, with other reactions, involves the production of a certain amount of trauma, which may lead to the partial or complete destruction of the cell, an effect which is now well recognized in the desquamation of the outermost layers of the skin after radiation. In the tissues of the eye a precisely similar reaction takes place; with small intensities of radiation the cells are injured, with great intensities they are destroyed. It is this end, under proper control, which is desired in the treatment of ulcers of the cornea, and the active response which the traumatism of light evokes repairs, and more than repairs, the damage which is done.

Histological studies carried out on the cornea of rabbits[2] which were subjected to radiation with ultra-violet light in doses considerably above those which may be used clinically, show no observable change after radiation until four hours have elapsed, when, in both the superficial and basal cells of the epithelium, some spacing out and oedema are evident. The nuclei of some of the more superficial cells then show the presence of acidophil granules, which take on a sharply defined eosin stain. After six hours these same changes are much more generally evident, and the arrangement of the superficial layers becomes somewhat irregular. The pathological changes are most striking after twelve hours. A large number of the nuclei of the epithelial cells take on the red stain markedly; some remain granular, in others the granules appear to have coalesced to form amorphous red "inclusion bodies," and a nucleus may contain a very large number of the former or be entirely converted into one or two of the latter. At a later stage these inclusions tend to bulge out the nuclear membrane, giving the nucleus a polymorphic shape, and finally they may be extruded altogether into the cytoplasm. Thereafter, if the cell is a superficial one, it appears to be cast off. At any stage before this the process may stop and the cell return to normal in appearance and staining reaction. From twelve to twenty-four hours after radiation desquamation is proceeding in the central area, around which there is frequently, but not invariably, a heaped-up region of proliferating epithelium. Meanwhile the substantia propria shows somewhat similar changes, which gradually decrease in intensity in the deeper layers, and from the limbus an infiltration spreads, composed very largely of cosinophils, although some polymorphonuclear cells are present. After thirty-six hours this limbal infiltration becomes more marked, blood spaces of considerable size are seen, and the cosinophils, which preponderated initially, are largely replaced by a massive invasion of polymorphs.

About fifty hours after radiation the epithelium near the periphery becomes more regularly arranged, and over the desquamated area a single layer of cells, the nuclei of which show no acidophil properties, begins to appear. The process of regeneration goes on with surprising rapidity and little evidence of cellular activity until, at seventy-six hours, the epithelium is two or three layers thick. At the limbus vascular infiltration is at its height; large new blood spaces, frequently surrounded by young fibroblasts, are present in great numbers, while the whole tissue in this region, and for some considerable distance into the cornea, is infiltrated with blood cells. This marked vascular reaction at the limbus seems to be a secondary feature, and is not evident histologically until the abiotic changes are well advanced; it is probably stimulated by the absorption of the products of protein disintegration. In seven days the cornea is again entirely normal.

Therapeutic Effects.

It is probable that the therapeutic effect of ultra-violet light when applied to the cornea in inflammatory, ulcerative, and degenerative conditions depends on the following factors. In the first place, pathogenic micro-organisms in the most superficial layers of this tissue will be directly killed. The lethal action of short-waved light upon such organisms is well known, and in a transparent tissue like the cornea this bactericidal power will be much more effective and extend more deeply than in an opaque and highly absorbent tissue like the skin. Where there is much inflammatory reaction and infiltration present in the superficial corneal layers, however, the greater part of the abiotically active rays will be absorbed, and in this case any lethal effect will necessarily be slight and practically restricted to the surface; but in proportion as some degree of transparency remains, bactericidal action will be greater and extend more deeply. In the second place, the superficial cells of the diseased corneal epithelium are killed and cast off with contained bacteria. Thirdly, the intense vascular reaction at the limbus and the invasion of the cornea by blood cells and inflammatory oedema will flood the diseased area with bactericidal influences. Fourthly, the stimulation to rapid and healthy regeneration of the exfoliated epithelium is a beneficial factor in any type of ulcer, but one which becomes of first importance in chronic and recurring conditions. Finally, it is probable that the absorption of the products of disintegration of the proteins of the cells will exert a favourable influence over the local immunological mechanism.

The Biological Action of Ultra-violet Light upon the Lens.

We have seen that the traumatization with the subsequent active response which ultra-violet light rays evoke, when used in clinical doses, is the action which is desired in the cornea. In the lens, however, the case is different. This is an avascular tissue in which active repair is comparatively lacking, and consequently any damage which may be done to it tends to be cumulative. Coagulation of the proteins of its cells is recognized clinically as cataract, a condition which has been produced experimentally by radiation with ultra-violet light.[3] With radiation of such intensity as does not produce an opacity, changes take place in the colloid system of this tissue which result in the proteins becoming more labile and their subsequent coagulation by other influences more easy. Moreover, the autoxidation system of the lens, upon which it probably depends in large measure for the maintenance and regulation of its metabolism, is damaged by ultra-violet light; while, in addition, the permeability of the capsule is

altered, thus further increasing the susceptibility to pathological changes. It has been urged that, in the comparatively small doses in which ultra-violet light is used clinically upon the eye, there is little fear of causing permanent damage to the lens; but it is to be remembered that small doses, such as have no apparent effect, produce physico-chemical changes which predispose to the formation of cataract. In addition, in many diseased eyes the possibility of a complicated cataract without any artificial stimulus is by no means remote. In any technique of local phototherapy, therefore, it is essential that the lens be excluded from the path of the incident rays.

Clinical Technique.

In the treatment of corneal ulcers by ultra-violet light the first essential is that the beam should be adequately controlled so that it may be limited to the diseased area; in this way unnecessary traumatism to the healthy parts of the cornea is avoided, and the lens is excluded altogether from the path of the rays. For this purpose I have introduced an "ophthalmic radiation lamp," which has been already described in detail elsewhere.[4] In principle it is a modified Gullstrand slit-lamp fitted with a mercury vapour lamp instead of the usual nitra lamp, and provided with an optical system of quartz, mounted on a freely movable arm. The last lens in this system is capable of accurate focusing and fine adjustment in two planes by means of an Arruga screw arrangement, and the precise incidence of the beam is controlled by observation through a Zeiss binocular corneal microscope. Interposed in the beam is an adjustable diaphragm and a system of filters, by means of which the nature of the light employed can be varied. For therapeutic purposes the ultra-violet light is employed unfiltered, but a screen which cuts off the abiotically active rays (such as uviol glass or Crookes's B) is useful for examinations for diagnostic purposes; with these all the advantages of a slit-lamp with red-free light are attained. With such an instrument a beam of considerable intensity and any desired size can be used, its incidence can be adequately observed and controlled, and in all cases it is easy to avoid the lens by inclining the beam at a sufficient angle. The most convenient procedure to adopt is to instil cocaine into the eye, which is followed by fluorescein, which is again washed out by cocaine. The patient is then set down to the radiation lamp, and, a uviol filter being interposed in the beam of light, the nature and extent of the ulcerative process are examined through the microscope. A remarkably beautiful and well-pronounced fluorescent effect is produced in this way, and the depth and extent of the disease are clearly delimited. The beam is adjusted so that it plays upon the ulcerated area, and no other region of the cornea, and the uviol filter is thereupon turned off and the unfiltered light allowed to play upon the eye. If the patient is unable to keep his eye open during the whole time of the treatment there is no disadvantage in interruptions, for intermittent exposures, within very wide limits, are additive in their effects, and have the same accumulative action as a single long exposure.

Other methods have been proposed from time to time. Koeppe (1919) and Birch-Hirschfeld (1922) employ a carbon arc as the source of light, but this emits a very large amount of heat; infra-red rays readily penetrate into the tissues of the eye and are potent for harm, especially to the lens, while any attempt to filter them off necessarily reduces the intensity of the abiotic rays. Ascher (1922) uses a quartz rod as a director along which the ultra-violet rays are guided, but although such a method is very suitable for radiating the conjunctiva it is impossible in this way, in the case of cornea, to control the beam of light with sufficient accuracy.

Dosage.

In radiating the cornea extreme care must be exercised with the dosage. I have found experimentally that the intensity of light required to produce a response is very slightly less than that required to produce an erythema upon the skin.[5] It is to be noted that, as occurs in the skin, the response varies with different individuals; consequently the ideal method is to test the erythema dose on the skin of the arm of each individual patient, and to commence radiating the cornea with a dose slightly less than this. In many corneal ulcers, however, it may be inadvisable to wait the twenty-four hours necessary for the development of the cutaneous reaction, and in these cases it may be necessary to start treatment immediately with an average dose. This may be taken as representing a period of radiation lasting three to three and a half minutes with the apparatus described, where the mercury vapour lamp is of the atmospheric pressure (K.B.B.) type, and runs on 220 volts, 2 to 3 amperes. Once the initial dose is obtained and its reaction observed subsequent doses are based upon it, but any increases are to be graduated with care, for it must be remembered that a small increase will make the difference between a mild and a violent photophthalmia.

Since the beam is always kept at a focus upon the cornea, the distance of the lamp from the cornea is constant, and the dosage can be altered only by time. Allowance must be made, however, for the obliquity of the rays, for it is evident that if the rays are not falling normally upon the cornea their intensity per unit area will decrease with the degree of obliquity. Actually, the energy varies quantitatively as the cosine of the angle of incidence of the beam, this angle being that which the incident ray makes with the normal to the tangential plane. The following table gives the factor by which the time of exposure determined for a normal ray should be multiplied in order to give an equivalent exposure with oblique rays:

Angle of incidence.	Cosine.	Factor.
0 (i.e., normal)	1.000	× 0.00
15 degrees	0.966	× 1.03
30 ,,	0.866	× 1.16
40 ,,	0.766	× 1.30
45 ,,	0.707	× 1.40
60 ,,	0.500	× 2.00

Some hours after the administration of a small exposure to a normal cornea there is a pricking sensation as of a foreign body in the eye, a sensation which is frequently accompanied by the appearance of haloes,[6] and which is followed by the symptoms characteristic of photophthalmia. After intense doses the pricking sensation gives way to pain, accompanied by marked photophobia, lacrymation, and blepharospasm. The appearance of haloes is due to corneal oedema; the pain is due to the irritation of the corneal nerve endings after the trauma to the epithelium. It follows that in those conditions where the epithelium has already been destroyed (as in the majority of ulcers) pain does not occur, provided the rays have been allowed to play on the ulcerated area only. The latent period which elapses before the reaction starts is about eight hours. In practice, therefore, when dealing with cases when a subsequent reaction is expected, it is well to conduct the treatment during the afternoon so that the symptoms begin to assert themselves during the night. If the patient has the eye bandaged up so that the lids do not abrade the radiated area, he frequently experiences no subjective symptoms at all, especially if a small dose of aspirin or bromide be given before going to bed to ensure sleep.

Clinical Indications.

Corneal ulcers of practically every kind respond well to radiation with ultra-violet light, but, inasmuch as the more simple types of ulceration tend to heal up with the usual methods of treatment, it is in the more severe, the chronic, and the recurrent forms that the beneficial effect of treatment can be seen to the best advantage. In the more simple forms healing without any opacity is usually obtained; and the method has been found extremely useful in cases of foreign bodies in which infection has already become evident. With the more severe types of ulceration radiational treatment is the method of choice. In hypopyon ulcers, for example, a greater chance of recovery is offered than can be expected from cauterization, with, at the same time, less permanent damage to the cornea. In a series of 190 cases of this type of ulcer published recently by Hoffmann at Königsberg the percentage of excisions of the eye was reduced to 4.6 from the percentage of 32 which obtained before radiational treatment was introduced. Chronic ulcers, also, associated with a varying degree of deep keratitis and corneal opacity, and sometimes with

iridocyclitis, in which the eye has reached a torpid and sluggish state, and which have progressed over long periods in spite of the usual treatment, may frequently be made to heal over and remain quiet after a course of three, four, or more exposures to light. The deep lesions of acne may also be very favourably influenced.

There are, however, two conditions wherein the beneficial effects of treatment are very evident: recurrent ulcers, and phlyctenular ulcers. With regard to the former, especially those marginal lesions associated with a continually relapsing conjunctivitis, the ulcer itself readily clears, an end which is, of course, usually easily brought about. But after the epithelium round the ulcer has been desquamated in the photophthalmic reaction following exposure to ultra-violet light, the new layer seems so healthy and resistant that it is enabled to withstand the liability to break down on future occasions. As a general rule the ulcer heals up after the first or second exposure, and in the milder cases heals up leaving a transparent facet: but it is preferable in most of these cases to give a third or fourth exposure, bringing about a mild reaction each time, involving a traumatism and renewal of the epithelium in order to render the possibility of recurrences more remote.

Acute phlyctenular ulcers occurring in children respond so well to general light treatment[7] and efficient dieting and hygiene that it is not worth while, as a rule, to coax a child affected with this disease to submit to keeping its eye open in the beam of the slit-lamp. It is in the chronic cases which have gone on for years, leaving an ulcerated, opaque, and vascularized cornea, and involving continued irritation, frequently with acute exacerbations, that the method has its greatest use. Here again it is best employed along with general light baths. In these cases the eye quietens down and becomes white and comfortable, but the extensive opacities, which are already present with the resulting diminution of vision, remain.

One word may be said with regard to corneal opacities. In order to investigate claims in the literature, a series of nine cases of old corneal opacities were given a fair trial with local radiation. No results justifying the continuation of the treatment were seen anywhere. It is certainly the case, however, that recent opacities, such as those following ulceration, may be improved, and the prophylactic action of the treatment of ulceration by light in the prevention of opacity formation is very marked. Two factors seem to enter into this: the rapidity of healing with new-formed epithelial cells, and the large amount of vascularization which the photophthalmic response excites. To this extent its action would seem to be comparable to that of an irritant, such as dionine.

FOCI AND NATURE OF INFECTION IN 100 CASES OF RHEUMATIC CONDITIONS.*

BY

E. CRONIN LOWE, M.B.E., M.B., B.S.,

PATHOLOGIST AND BACTERIOLOGIST TO SOUTHPORT INFIRMARY AND LIVERPOOL EYE AND EAR INFIRMARY.

(*With Special Plate.*)

IT is now admitted that a large majority of rheumatic cases are due to some infective cause. Many types of organisms have been accredited with being the causal agents, but it has also been admitted that no one organism has proved to be the causal factor in more than a certain number of cases. Similarly, with regard to the focus held to be responsible in cases of infective arthritis and fibrositis: teeth, tonsils, accessory sinuses, gall-bladder, intestinal tract, and urinary and genital passages have all in turn fallen under suspicion as being the main or primary source of infection, and treatments designed to deal with these foci have sometimes been applied with good results, but more often without success.

It has generally been realized that while unhealthy and abnormal conditions of any of the areas above enumerated may be the cause of arthritis, fibrositis, myositis, neuritis, and other inflammatory conditions, it is exceedingly difficult to determine in any individual case whether the particular area under consideration is really the causal one, or whether it is only one of several equally important foci which may be present, but less obvious, in the patient. The bacteriological investigation of specimens from a patient suffering from some rheumatic infective condition, as indeed from an apparently normal person, will show numbers of varying strains of organisms in cultures made from teeth, tonsils, sinuses, post-nasal secretions, faeces, etc., and many of the isolated bacteria are of a possibly infective type and character. In the normal person they are obviously not so at the time, and the question arises of how to decide which, if any, are of infective importance to the patient under investigation. In the rheumatic case it is usually assumed that streptococci, if isolated, are probably causal, and past experience in treatment has certainly shown this conclusion to be frequently correct; but the types of streptococci are many and various, and the question again arises as to whether they are all of equal importance to the case from which they have been isolated, or whether one or other strain is the real causal agent of the condition present.

A great deal of work has been done on the bacteriology of rheumatic infection during the past thirty years. Paino and Poynton[1] claimed the organism they isolated and named *Micrococcus rheumaticus* to be the specific infective agent; Andrewes and Horder[2] later recognized this organism as probably similar to the *Streptococcus faecalis*. Shaw,[3] and later Beattie,[4] demonstrated the presence of streptococci in the synovial membranes of cases of acute rheumatism, and with these experimentally reproduced arthritis and endocarditis in rabbits; Topley and Weir,[5] however, showed that not only streptococci isolated from rheumatic lesions, but those from non-rheumatic sources, were capable of producing similar experimental lesions in rabbits. Warren Crowe[6] described a staphylococcal type of organism, which he named *Micrococcus deformans*, and believed it was frequently a specific cause of infection in chronic infective arthritis. Bach and Wheeler[7] have quoted many cases in which chronic intestinal infection, associated with the presence of atypical coliform organisms, has apparently been causal in certain forms of rheumatism. Ford Robertson,[8] after giving his reasons for not accepting the *Micrococcus rheumaticus* as an adequate specific agent, detailed several different species—namely, *Streptococcus pyogenes, anginosus, salivarius, B. influenzae, pneumococci, diphtheroid bacilli*, and *Micrococcus catarrhalis*—which he considered were all capable of being causal agents in rheumatic infections. Some indecision exists, therefore, as to which, if any, of the numerous organisms isolated from a case may be pathogenic to the patient concerned, and, further, as to which organisms should be employed as an antigen in the condition, if vaccine treatment is desired.

In approaching the question of ascertaining the focus and bacteria concerned in rheumatic cases, these difficulties were appreciated, and in view of the satisfactory results obtained by means of the pathogen selective culture method in previous cases already published (Solis-Cohen[9] and Cronin Lowe[10]), this method of bacteriological examination was carried out in a large number of cases which clinically fell into the group of rheumatic infections. An analysis of the findings in 100 of these cases is the subject of this communication.

* Communication read before the Wallasey Medical Society, March, 1929.

The pathogen selective method has been explained in detail elsewhere[10]; it depends upon employing the patient's freshly drawn blood to determine, by the presence or absence of efficient bactericidal power, whether any of the organisms present in suspected foci of infection are or are not pathogenic to the patient concerned. The method has several practical advantages. (1) It allows of many foci being examined at one sitting. In this group of 100 cases an average of three specimens in each patient was examined, the maximum being six and the minimum two. (2) It differentiates between foci which are causing systemic infection of the patient and those which are not doing so, at the time of examination. (3) It selects the organisms in such foci which are responsible for the systemic infection in certain cases, sometimes indicating one particular strain as the only important pathogenic agent in the patient infected.

The various specimens examined were classified according to the types of pathogen selective findings which resulted, and it was found that while a quarter of the total examinations gave evidence of a multiple or dual infection, and another quarter of no infection at all, practically half the specimens examined indicated that a single pathogenic micro-organism was the active infective agent. The appearance of these bacteriological results may be shown in the photographs of actual culture plates, demonstrating each of the findings enumerated. (Figs. 1 to 5.)

Clinically the cases of this series comprise infective arthritis 51, fibrositis 39, chronic neuritis 7, and sciatica 3 cases. In many of these cases full bacteriological examinations were made upon dental, tonsil, post-nasal, antral, intestinal, urinary and cervical (uterine) specimens wherever possible. An analysis of the specimens examined shows that in 20 cases two specimens were dealt with; in 55 cases three specimens; in 22 cases four specimens; in one case five specimens; and in 2 cases six specimens.

In Table I the number of cases in which more than one infective focus was shown to be present are detailed; in the lower section is shown how rarely a single focus is wholly responsible. These findings appear to emphasize

TABLE I.—*Positive Pathogen Selective Findings in 100 Cases of Rheumatic Infection.*

In 28 cases positive cultures occurred in	1	specimen only.
In 47	,,	,,	,,	,,	2 specimens only.
In 21	,,	,,	,,	,,	3 ,, ,,
In 4	,,	,,	,,	,,	4 ,, ,,

Thus in 100 cases positive cultures occurred in 201 specimens.

The 28 cases in which positive pathogen cultures resulted in one specimen only suggests that the foci responsible for infection were intestinal in 10 cases, post-nasal in 9 cases, tonsillar in 6 cases, and dental in 3 cases. In the remaining 72 cases more than one focus was responsible for, or contributed to, the generalized infection present.

the importance of making a wide search in any and every case of suspected infection, for frequently a pathogenic focus has been found in an area showing no clinical evidence of infection. It is possible that in the 28 cases with a single focus of infection cure of the disease might have been obtained by eradicating the focus, but it is almost certain that in the remaining 72 cases more extensive and more general means of treatment was called for.

Table II shows in more detail the numbers and percentages of positive pathogen selective findings obtained from various foci examined, and indicates that roughly two-thirds gave some type of positive findings and one-third gave negative results. It will be noted that very

TABLE II.—*Comparative Frequency of Positive Pathogen Selective Cultures in Specimens Examined from Foci in 100 Cases of Rheumatic Infection.*

few cervical examinations were made; there was, however, very little evidence of cervicitis, although it was inquired for in all women examined. The small percentage of pathogenic findings in catheter urine specimens is also of interest, confirming what has been emphasized elsewhere, that the mere presence of bacteria in a specimen of urine does not necessarily mean that they are an infective agent.

Table III further summarizes the relative clinical importance of potential infective foci as indicated by pathogen selective cultures in these 100 cases, and corresponds with

TABLE III.—*Showing the Relative Clinical Importance of Potential Infective Foci in 100 Cases of Rheumatic Infection.*

Foci Examined.	Number.	Positive Pathogen Selective Cultures in 308 Examinations.

the evidence of other observers that infective foci associated with the upper respiratory tract are the most frequently responsible for rheumatic infection conditions, while those of the intestinal tract come second, with tonsillar and dental foci taking third and fourth place respectively.

Table IV is introduced as a contrast, in which the completely negative pathogen selective findings resulted from similar examinations in 7 cases other than the 100 analysed, and in which subsequent clinical evidence confirmed that they were not cases of infective rheumatism.

So far, I have attempted to indicate that it would appear possible to determine in cases of chronic infective disease which of several possible foci under consideration harboured bacteria capable of causing systemic infection to the patient concerned.

In Table V is shown a comparison of the incidence of organisms isolated by the pathogen selective cultures with their incidence in direct or ordinary cultures; the frequency with which they appeared in the various foci is also shown.

It would appear that while any organism may be pathogenic to a particular patient, the *catarrhalis*, diphtheroid, atypical coliform, and *B. influenzae* groups are comparatively rarely of pathogenic importance. The streptococcal, pneumococcal, staphylococcal, and coliform groups are not only the more commonly pathogenic organisms, but their percentage frequency in infective foci is about the same. Further, the pathogen selective culture method is not selective of one or other organism only, but, as demonstrated in these findings, it will select any of the ordinarily present strains to which the tissues of the patient have lost their bactericidal protection.

It has been objected to this form of examination that it is merely using an enriched and therefore selective medium. This contention is not borne out by these findings, for they clearly show that while the organisms have in some cases been isolated, they have with equal, or greater, frequency been inhibited. In some specimens one patient's blood is inhibitory to certain organisms and favourable to others, while the blood from another patient results in an exactly opposite selection; Solis-Cohen's view that these

findings are dependent upon the presence or absence of efficient bactericidal power in the blood concerned appears to be confirmed by the details given above.

In Table VI is given the comparative frequency with which the various organisms detailed were isolated by the pathogen selective cultures, and it is of some interest to compare these findings, both as regards the organisms themselves and the numerical frequency of their isolation, with those of the many workers referred to earlier in this paper and to note the significant correspondence. As would be expected, streptococci as a group occur most frequently, especially the haemolytic types, both *pyogenes* and *anginosus*, while the *Streptococcus faecalis* of Andrewes and Horder is next in importance. Practically all the organisms which various writers have accredited with infective importance in rheumatic conditions have been selected, in one case or another, as pathogenic to the patient concerned, and it is striking to find Ford Robertson's[8] list of infective species in chronic rheumatism so closely and fully repeated.

TABLE VI.—*Percentage of Total Pathogen Selective Cultures isolated from 100 Cases of Rheumatic Infection.*

B. influenzae		2%
Diphtheroid bacillus		0.3%

SUMMARY.

1. One hundred cases of varying degrees and types of rheumatic disorder have been examined for evidence of focal and bacterial infection, employing the pathogen selective culture method.

2. An average of three specimens were examined in each case.

3. In 28 cases only one infective focus was suggested by the pathogen selective method from the several specimens examined in each case.

4. In 72 cases more than one focus was apparently responsible for some proportion of the infection.

5. Taking all the cases together the clinical importance of infective foci was shown to be in the following order: post-nasal and accessory sinuses first, then intestinal, tonsillar, and dental foci.

6. As regards the actual infective organisms the streptococcal group was markedly predominant, but practically any other commonly present organisms may be important in an individual case.

7. It is apparently possible to determine which or how many of various suspicious foci in any patient are infectious and which are not, and thereby radical or conservative treatment may be clearly indicated in any case.

8. The actual organisms present against which the patient has lost resistance and for which an adequate immunity should be developed is indicated, and makes possible the employment of rational and exact vaccine therapy.

No attempt is made in this paper to elaborate the results of treatment as shown by repeating pathogen selective cultures at later dates, but it is hoped to detail these very satisfactory results in a later communication.

CONGENITAL DIAPHRAGMATIC HERNIA.

BY

G. D. F. McFADDEN, M.CH., F.R.C.S.ENG.,

ASSISTANT SURGEON, ULSTER HOSPITAL FOR CHILDREN, BELFAST.

(*With Special Plate.*)

CONGENITAL diaphragmatic hernia is not a common condition, and it is rarely that a case presents itself with sufficient salient points for a diagnosis to be made in the clinical examination. The diagnosis can, as a rule, be made only in the *x*-ray department or in the operating theatre.

A boy, aged 4½ years, had been a premature child, and delicate since birth. He had no acute upset in his health till six weeks before he was seen by me at the Ulster Hospital for Children. In his first attack he suddenly screamed out with acute pain referred to the lower abdomen. He afterwards vomited. The pain and the vomiting continued and became more severe the following day. The bowels did not move even after repeated enemata. The third day the bowels moved and vomiting ceased. The pain lessened and finally disappeared. The boy was quite well till two weeks later, when he had a similar attack, which was less severe and lasted two days. Four days before I saw him he had another attack, from which he had not recovered when seen. This attack was like the others, but more severe. The mother had never noticed any fits of blueness or of breathlessness.

On examination the patient was seen to be a boy of delicate make, but not so ill as one would have expected a child to be with acute intestinal obstruction lasting four days. The colour was normal, with no signs of cyanosis. The pulse was 120, and the temperature normal. The abdomen was small and retracted, and appeared empty. The recti muscles stood out like a bow-string, especially during an attack of pain. The abdomen felt empty; no lump could be detected. The empty abdomen and the history of intestinal obstruction suggested the diagnosis of a diaphragmatic hernia. The chest showed diminished resonance over the base of the left lung, and the heart was slightly displaced to the right. There were no breath sounds to be heard

over the dull area, but occasionally a sound suggestive of an intestinal gurgle was heard. The diagnosis of a diaphragmatic hernia was made, and the child sent to the *x*-ray room for confirmation of the diagnosis.

A barium meal showed the stomach to be normal and in its usual position, but the left lung was collapsed into the apex of the left pleural cavity. A second radiogram (Fig. 3) showed the gas-filled colon and intestines in the pleural cavity. The patient was given glucose and sodium bicarbonate by the rectum to lower acidosis and prepare him for operation.

Operation.

An oblique incision was made from the ninth intercostal space downwards and forwards to the umbilicus. The upper part of the incision passed through all the musculature and the peritoneum. In the lower part the anterior and the posterior leaves of the rectus sheath were incised and the muscle pulled medially. The intestines were found passing through an opening in the diaphragm. The opening extended forward as far as the tenth intercostal space and was about two inches in diameter. The abdominal incision was continued through the tenth intercostal space so as to pass through this opening. By pulling from below and pushing from above, the contents (all the small intestine from the duodenum to the caecum, two-thirds of the colon, and a large part of the omentum) were reduced into the abdomen. The omentum was adherent to the edges of the opening, but was easily detached. The intestine was normal in appearance. The opening in the diaphragm was easily closed by continuous forty-day catgut suture. The intercostal opening was closed by interrupted catgut sutures passing above the tenth rib and below the eleventh rib. The remainder of the wound was then closed by suturing the layers in the usual manner. The child stood the operation well considering he was not a robust child.

An intravenous glucose saline, administered by Dr. Hilton Stewart during the operation, undoubtedly helped the patient. The boy's convalescence was uneventful.

Clinical Examination.

A radiogram taken ten days after the operation showed that the lung on the left side had returned to normal (Fig. 4).

Points of Interest in the Case.

1. Although the opening was evidently congenital the patient had no symptoms due to it till he was 4 years old. A thin membrane may have prevented herniation.
2. The symptoms were all referred to the abdomen.
3. The incision, planned so as to pass through the hernial orifice, made the reduction easy, and it did not appear to cause unnecessary shock.
4. The hernia was of the type most commonly found. It was situated on the left side at the point where the two embryonic migratory muscle elements meet—that is, those fibres developed from the ventral longitudinal muscles sheet and those from the subvertebral muscle mass. There was no peritoneal sac.
5. The contents were small and large intestines and omentum. The stomach and spleen were in their normal position.
6. The pleural cavity was opened without respiratory disturbance due to mediastinal adhesions.
7. The lung re-expanded without positive intratracheal pressure, and in spite of the irritation of that half of the diaphragm due to the surgical intervention.

A CASE OF MENINGOCELE.

BY

B. PICKERING PICK, O.B.E., M.R.C.S., L.R.C.P.,

SURGEON COMMANDER R.N.,

ROYAL NAVAL HOSPITAL, CHATHAM.

(*With Special Plate.*)

THE following case must be of sufficient rarity to warrant its publication.

A warrant officer in the army, aged 32, first came under notice on May 26th, 1928, complaining of acute lumbar pain of ten to twelve days' duration. The onset had been sudden and was becoming progressively worse. Pain was also felt in the left knee. There was nothing of interest in his previous medical history except that he had had difficulty since birth in obtaining an action of the bowels. When first seen there had been no action for five days, in spite of purges and the administration of enemata, which had been retained. The passage of a rectal tube had produced a little flatus with some slight relief.

On examination the temperature was 102°, and he was complaining of headache. He was tender in the lumbar region and over both sacro-iliac joints, the tenderness corresponding with the site of pain. The abdomen was distended and hyper-resonant on percussion. No mass could be felt in the abdomen, but on rectal examination a large swelling could be felt behind the rectum; its limits, however, could not be determined by the examining finger. There was no abnormality of the urine. A blood count showed:

Red cells (per c.mm.)	3,490,000
White cells (per c.mm.)	6,400
Haemoglobin	85 per cent.
Colour index	1.2
Differential count:	
Polymorphonuclears	81 per cent.
Lymphocytes	15 ,,
Large mononuclears	4. ,,

May 27th. The patient was anaesthetized and placed in the lithotomy position. On examination the swelling felt cystic. It was tapped and 30 ounces of slightly opalescent fluid was drawn off. The fluid was subsequently reported on as follows: "Specific gravity 1008; neutral; serum globulin and serum albumin present; 250 mg. sugar per 100 c.cm.; urea above 20 mg. per 100 c.cm. The fluid appears to be cerebro-spinal in origin and slightly altered." As a result of emptying the cyst the obstruction was relieved and the distension was diminished. A more extensive examination was now possible, and it was found that the coccyx and a great part of the sacrum were missing. A subsequent *x*-ray examination confirmed this, and the radiologist suggested that "it was a congenital deformity, as there was no evidence of disease in the remaining bones."

May 28th. The patient had a good night on the whole, but had had a severe headache lasting about ten minutes. Bowels opened naturally. The abdomen was again somewhat distended and palpation in the lower part caused severe headache. The cyst had filled up again.

May 29th. In the evening slight retraction of the head was noted and there was slight opisthotonos. Kernig's sign was present. No abdominal reflexes obtained. A throat swab was negative to meningococcus.

May 30th: Severe headache and distress.

May 31st. Retraction more marked, and patient complained of cramps in the legs. Seen by Mr. Arthur Edmonds, who recommended aspiration of the cyst and irrigation with acriflavine. This was done under general anaesthesia, and examination of the fluid gave the following result. Deposit of pus. Organisms: (1) Gram-negative organisms, probably *B. coli*. (2) Gram-negative intracellular diplococci. No growth on media in sixteen hours.

June 1st. Had a fair night, but some intense headache at times. He was quite clear mentally, but the signs were more marked. The cyst was treated as before. Lumbar puncture was performed and turbid fluid, which was not under pressure, was withdrawn. On examination the fluid showed: Cell count 2,240. An abundance of polymorphonuclear leucocytes and some Gram-negative bacilli. No growth; 25 c.cm. of *B. coli* serum given subcutaneously.

June 2nd. Lumbar puncture repeated. The fluid contained a large deposit of pus; cell count 19,000 per c.mm. Numerous organisms, mostly Gram-negative bacilli, but also some Gram-positive cocci; 25 c.cm. of serum given intrathecally, the same amount having been given subcutaneously earlier in the day. Patient had some difficulty in swallowing.

June 3rd. Patient had a very good night and swallowing was easier. He moved less stiffly in bed and could move the head from side to side. Read the paper and talked intelligently. Operations as before, but there was no fluid from the lumbar puncture.

June 4th. A fair night, but at 4 a.m. patient became pulseless. He recovered and slept. There was no change in the signs, and leakage from the cyst in the coccygeal region was noted. He had a rigor at midday. Only a small drop of fluid was obtained by lumbar puncture. Serum given as before.

June 5th. Patient had had six and a half hours' sleep and said he was quite comfortable. He was quite rational. Pulse 160, and respirations rapid. Incontinence of urine. In the evening he was much worse and obviously dying. He became slightly delirious before death.

A post-mortem examination was held fifteen hours after death. The body was fairly well nourished. The meninges were very adherent to the skull. Cerebro-spinal fluid was scanty and almost clear. Meninges very little changed. Some oedema of pia mater on the surface of the brain, which showed nothing abnormal. On opening the abdomen the peritoneum and intestines appeared healthy. A swelling the size of a coco-nut was present in the mid-line of the pelvis and adherent to rectum and sacrum. Some sacral vertebrae and the whole coccyx were missing. The cyst contained a greenish glairy fluid and its walls were smooth and congested. It was realized that there must have been some communication with the neurenteric canal, but this was not demonstrated.

Two of the children have always suffered from constipation, but do not show any trace of the abnormality from which their father suffered.

IMPACTED CYST IN THIRD VENTRICLE OF BRAIN.

REPORT OF TWO CASES.

BY

A. M. DRENNAN, M.D., F.R.C.P.ED.

(From the Department of Pathology, University of Otago Medical School, Dunedin, New Zealand.)

(With Special Plate.)

DURING a period of ten years two most unusual cases of cyst of the choroid plexus in the third ventricle have come to necropsy. Both patients died rapidly and formed the subjects of coroners' inquests, so that it seemed desirable to place the cases on record.

In searching the literature at my disposal I have been able to find but few records of similar cases. It is true that the pathological condition of cyst of the choroid plexus is referred to in pathological textbooks, but it is usually dismissed as being of little practical importance. J. H. Douty[1] described a case of "villous tumour" of the fourth ventricle which appeared to have the structure of the choroid plexus and which blocked the fourth ventricle. It occurred in a lad of 17 years, who had a history of reeling gait and gradually increasing weakness for months. The late Sir Frederick Mott with J. O. Wakelin Barratt,[2] in recording three cases of tumour of the third ventricle, found one of these to be a cyst which filled the third ventricle and had the structure of choroid plexus with a gelatinous content. The patient was a man, aged 34, who had attacks of severe headache, double vision, ptosis, and stupor. The condition persisted for about seven months, and he finally became comatose and died. Buzzard and Greenfield,[3] in their book (p. 259), illustrate "a colloid tumour of the third ventricle, possibly derived from the pituitary." The gross appearance of this is very similar to Case ii, described below.

CASE I.

The patient was an unmarried girl, aged 19. She had a history of headaches at intervals and attacks of faintness, the first said to have been about two years previously. On November 15th, 1919, she complained of pain in the head. During the night her parents applied cold cloths to relieve the headache. About 6 a.m. on November 16th she became worse and finally unconscious. A doctor was called, but on arrival he found the patient dead. The coroner ordered a post-mortem examination and held an inquest.

Post-mortem Examination.—The body was that of a well-developed and well-nourished young woman. There was pronounced post-mortem lividity in dependent parts and in the neck. On reflecting the scalp there were small pin-point haemorrhages in the scalp tissue over the right frontal region and in the occipital region. The brain showed flattening of the convolutions on both sides; there was no meningitis, and no adhesions were present. There was slight engorgement of the surface vessels and excess of clear cerebro-spinal fluid at the base. On section the brain tissue was very oedematous, with moderate engorgement of the vessels in both white and grey matter. The lateral ventricles were slightly dilated and filled with clear cerebro-spinal fluid. Lying in and completely blocking the third ventricle was a clear-walled cyst, the size of a large pea, attached to the choroid plexus at the anterior end of the third ventricle. The cyst could be dislodged, and was then freely movable except at its attachment to the choroid. In the choroid plexus of the right lateral ventricle was a similar but much smaller cyst. The spinal cord was oedematous. There was nothing of special note in the other organs, except an old encapsulated caseous nodule, 2 cm. in diameter, in the lower part of the upper lobe of the right lung.

Summary.—Cyst of choroid plexus blocking the third ventricle; acute hydrocephalus; acute cerebral oedema.

Microscopical Examination (see Fig. 3).—Portions of the choroid plexus and of the cyst wall were cut. The choroid plexus has the usual structure—namely, a scanty and loose areolar tissue in which are many small vessels and capillaries; covering the plications of the plexus are the ependymal cells. The wall proper of the cyst consists of a thin layer of connective tissue on which is a layer of clear cells, cubical to flat, similar to the ependymal cells of the choroid plexus adjacent. The content of the cyst has a homogeneous hyaline structure; in parts are a few scattered cells, some polymorph leucocytes, some mononuclear in type and difficult to identify.

CASE II.

The patient was a young man, aged 23, unmarried, a porter in a hotel. No history was obtainable of fits or illnesses of any kind, except a "strain" about a year previously; judging by the operation scar seen at necropsy this seems to have been an inguinal hernia which had been cured by operation. The family history was not good; his mother was said to have been a prostitute, one brother was in an asylum with general paralysis of the insane, and another brother was known to be addicted to drink.

On June 24th, 1928, the patient, who had been out, returned about 11 p.m. apparently in good health, and retired to bed. At 6.30 the following morning he was found by one of the hotel servants lying on his bed—which he had put on the floor—groaning and barely conscious. He had been sick out of the window and on the floor, and his bowels had moved. He was put back in his bed, and when visited about a quarter of an hour later was found to be dead. The police were informed, and the coroner ordered a post-mortem examination and later held an inquest.

Post-mortem Examination.—The body was that of a well-developed, strongly built young man. Rigor mortis was general throughout the body. There was the usual post-mortem lividity in dependent parts of the body. There was a slight bruise at the root of the nose towards the left side, and two small and quite superficial abrasions on the left side of the forehead. There were no other marks of injury, except a partially healed cut on the left hand and an old operation wound in the right groin. All the teeth of the upper jaw were absent, but no dental plate was present in the mouth, or elsewhere in the body. There was no obstruction in the upper air passages; the trachea contained scanty, frothy mucus; the oesophagus was empty. The thoracic and abdominal organs were healthy. The stomach was contracted, its mucous coat was covered with mucus and a few food remnants and was slightly congested.

Head: The skull cap was normal. *Brain:* The dura stripped readily and appeared healthy. There was slight excess of cerebro-spinal fluid around the base. The cerebral arteries appeared healthy. The surface convolutions were flattened. On section the brain substance was markedly oedematous and the lateral ventricles were moderately dilated and filled with clear cerebro-spinal fluid. In the mid-line was a round, clear-walled cyst firmly plugging the third ventricle; it was attached to the adjacent part of the choroid plexus of the ventricle. The illustration (Fig. 1) shows the appearance of the brain when cut horizontally through the plane of the cyst.

Microscopical Examination (see Fig. 2).—The appearances are the same as already described in the first case. The illustration shows a portion of the cyst wall, part of the homogeneous content, and some of the lining cells cut tangentially. Many of these cells are distended with granular content, staining pale lilac in the haematein-eosin section; the cyst content at its margin shows similar globules of granular material, as if composed of cells whose nuclei had disappeared. The amorphous content of the cyst stained blue with Leishman's stain and with toluidin-blue.

Summary.—Death in coma caused by a cyst of the choroid plexus of the third ventricle suddenly blocking that ventricle and causing an acute hydrocephalus and acute cerebral oedema.

The Wassermann and hydatid complement fixation tests were negative.

Commentary.

These two cases are interesting from both the pathological and the medico-legal point of view. Such cysts of the choroid plexuses are not unusual in the lateral ventricles, but apparently rare in the third ventricle. In both these cases it would appear as if the cysts had occurred at or near the apex of the third ventricle and had been freely movable; owing to this they had become impacted, with resulting oedema leading to firmer impaction and complete blockage of the ventricle; this in turn led to the acute hydrocephalus. The appearance of the content of the cysts suggests that it was formed partly by the activity of the lining cells and partly by serous transudation. The origin of the cysts is from the choroid plexus, judging by the microscopical structure; the exact mode of formation cannot be stated from the data available. The few inflammatory cells seen in the content are probably of terminal origin only, and there was no evidence found of previous inflammatory change.

THE EARLY DIAGNOSIS OF PERNICIOUS ANAEMIA BY THE HALOMETER.

BY

FRANK C. EVE, M.D., F.R.C.P.,

SENIOR CONSULTING PHYSICIAN, HULL ROYAL INFIRMARY; SENIOR PHYSICIAN, VICTORIA HOSPITAL FOR SICK CHILDREN, HULL.

THE position of patients suffering from pernicious anaemia has lately been revolutionized by two discoveries: (1) the curative effect of liver and hydrochloric acid; (2) the diagnosis of pernicious anaemia by finding enlargement of the red cells (Price-Jones)—a feature which is always present, and which, apparently, is the first to appear and the last to go. By the halometer, a clinical instrument which instantly measures the size of the red cells, this latter diagnostic information becomes available to the general practitioner for the first time, and the liver cure can be instituted at a far earlier stage. Hence no more patients need be allowed to reach the stage of pallor or lemon colour.

These remarks apply also to subacute combined degeneration of the spinal cord, but not so absolutely, because occasionally the neurotoxic factor in pernicious anaemia is at first unaccompanied by the haemolytic. In both cases the poison originates from streptococci which have obtained a foothold in the upper bowel owing to the absence of hydrochloric acid in the stomach, which, had it been present, would almost infallibly have killed them there (A. F. Hurst). Achlorhydria is thus almost invariably a diagnostic feature of these two diseases. Achlorhydria is present from birth in 4 *per cent.* of normal people, who are unconscious of their danger. The streptococci are found in the tooth sockets (always unhealthy), and they generally cause glossitis. Hence our fourfold course of action to stop these diseases, long before anaemia is evident, is quite clear and logical:

1. In all suspicious cases ascertain if the red cells are enlarged (for example, by the halometer). If so, confirm by the colour index, or prove achlorhydria by a fractional test meal.
2. Should the latter investigation be unobtainable give daily half a pound of liver, or the corresponding amount of its extract, and if this causes the red cells to become normal in size in about two months the diagnosis of pernicious anaemia is established.
3. Extract suspicious teeth; remove septic tonsils or keep them clean by my suction method.*
4. Give 6 drachms of dilute hydrochloric acid daily, diluted with a pint and a half of water and flavoured with orange juice and sugar. Half a pint of this is taken three times a day on an empty stomach, and is known to kill the streptococci in twenty minutes. The results are usually miraculous, but relapse follows if the liver diet is omitted. Hence the halometer must be used every three months to ensure that the red cells remain normal in size. Hydrochloric acid must be taken for life to prevent streptococci from again obtaining a foothold in the upper bowel. Theoretically it should then be unnecessary to continue the liver treatment if periodical examination by the halometer shows red cells of normal size; but until we know more it is safer to continue it.

The first essential is to make the diagnosis of pernicious anaemia or spinal degeneration in the earliest stages, before tissue degeneration has damaged heart, cord, or other organs, or made it impossible for liver treatment to save life. As the diagnosis can now be made in a few seconds from a thin blood smear, it is not too much to expect that the size of the red cells should always be estimated in the following disorders: (1) anaemia, of which the cause is not evident; (2) chronic glossitis; (3) obscure cases of loss of strength and flesh; (4) achlorhydria (often present in cholecystitis, chronic appendicitis, and rheumatoid arthritis); (5) bleeding from the bowel ("piles"); (6) loss of power or sensation in the legs, which might be due to spinal degeneration; and (7) tingling in the hands or feet—often a sign of early spinal degeneration.

The use of the diagnostic instrument now to be described provides unsuspected opportunities of employing liver with success, and reveals a condition which might be called "pre-pernicious anaemia."

* See *British Medical Journal*, June 2nd, 1928, p. 941.

MEASUREMENT OF RED BLOOD CORPUSCLES.

Theory of the Method.—A thin blood smear acts as a very efficient diffraction grating and splits up the rays from a small source of light into a brightly coloured halo like a circular rainbow (Pijper). A halo round the moon is formed similarly by the presence in the air of fine water particles. The smaller the particles the larger the halo, and vice versa (T. Young), so that the large red cells characteristic of pernicious anaemia produce a halo which is smaller than the normal.

*The Halometer.**

This clinical instrument has been designed to enable the practitioner to measure the average size of the red cells quickly and easily, and thus to make an early diagnosis of pernicious anaemia and allied conditions. It consists of a tiny electric bulb of which the illumination (by a battery included in the instrument) is regulated by a graduated switch until it is just white and no longer reddish. The whole is encased in a small black box with a hole at one end against which the blood smear is clipped and through which the light is then seen surrounded by a coloured halo. To facilitate the estimation of the diameter of the halo it is duplicated by reflection from a pair of inclined mirrors, and the movement of a knob along a scale at the side of the box causes the haloes to approach each other until their red edges are just brought into contact. The scale now records a measure of the diameter of the halo. The calibration gives the angular measure of the halo, but the reading can be converted into the average size of the red cells by reference to a printed table. Except for comparison with other methods this is redundant, as the limits of normal blood are clearly indicated on the scale. By experience of a large number of blood smears I am able to make the following generalizations:

1. Normal blood haloes are 4.6 degrees to 4.9 degrees.
2. Blood haloes in definite pernicious anaemia or subacute combined degeneration are 4.4 degrees or less.
3. Blood haloes round and about 4.5 degrees are suspicious (confirm by achlorhydria, etc.).
4. Those of infants and in cases of polycythaemia and familial acholuric jaundice are usually over 5 degrees.
5. Cases of pernicious anaemia in an advanced stage yield hazy, very small, colourless haloes.
6. Hazy colourless haloes of normal size are characteristic of severe secondary anaemia.

In both (5) and (6) the lack of colour and definition is due to the irregularity in shape and size of the red cells, which naturally impairs the perfection with which they diffract the beam of light. It is better, perhaps, to confirm this by examining the film (unstained and not covered) with a 1/6 in. objective, partly to ensure that the film is only one cell in thickness. But I seldom find this proceeding necessary. Thick films are unreliable.

At first I used an ordinary reflex camera for blood halo work; later I realized that the human eye is the only camera required, and the halometer merely measures the diffraction halo produced on the retina. It is cheaper and more accurate than a camera, packs into a doctor's bag, and is independent of outside sources of illumination. The graduations on the scale of the halometer are all equal, so that if the normal graduation is correctly placed all other results are uniform.

To make a thin blood smear the essentials are: (1) clean grease-free glass slides, and (2) to push the inclined slide—and with it the blood—along the horizontal one, not pull it. Either the slides should be kept in ether or placed on a clean table with a drop of absolute alcohol or ether on each, and rubbed vigorously with a wad of absorbent wool. Better still, I find, is to clean off an old blood smear with wet cotton-wool and then dry lightly with a towel. The residual trace of albumin ensures a beautiful thin even blood film.

A small drop of blood (2 mm.) from the nail base of the warm thumb is touched on to one end of a slide. The end of another slide is dipped into the drop, which should quickly spread all along the edge. This slide is then firmly pushed, like a plane, along the first slide, leaving a broad thin film of blood. The best part of the best film is

* The halometer owes much to the ingenuity of Dr. Stenhouse Stewart and of the manufacturers (the Ellis Optical Co. of Croydon). It is obtainable from Messrs. Down Bros., St. Thomas Street, London, or Allen and Hanburys, Wigmore Street. Price £4 4s.

applied to the hole in the end of the halometer. The halo diameter and the date are recorded on the label of the slide, and kept so that the progress on liver diet may be noted. Most red cells preserve their size indefinitely, but I think that where the plasma is relatively abundant (as in severe pernicious anaemia) the red cells must be very slowly stretched in the course of weeks by shrinking of the plasma film; so it is well to measure (or post) the film without many days' delay. I do not heat the films.

PRE-PERNICIOUS ANAEMIA.

Our former conceptions of pernicious anaemia apply only to the late stages; the early stages are quite different. Enlargement of the red cells is the first reliable sign; anaemia is then slight, and is only shown by a small deficiency of haemoglobin. The pathologist may report "blood film normal, slight secondary anaemia, colour index well below unity." The usual overfilling of the red cell with haemoglobin has often not begun; nor has haemolysis, for the van den Bergh test is negative. In this early stage the patients are usually florid and well nourished, so that everyone is incredulous when anaemia of any sort is diagnosed. In fact, the term "pernicious anaemia" is inappropriate in the early stage revealed by enlargement of the red cells, and a special name is needed, such as "pre-pernicious anaemia." This condition would progress to the familiar pernicious stage if left untreated, for achlorhydria is almost invariably found, sore tongue is usual, and the size of the red cells soon becomes normal under liver treatment, which is known scarcely to influence other anaemias.

Similarly, subacute combined degeneration of the cord can usually be recognized by the enlarged red cells (because the neurotoxic and haemolytic toxins generally act in concert) at a far earlier stage than has hitherto been clinically possible. In the space of a year I have thus identified three cases, in which the patients complained solely of tingling of the hands and feet. This is a great advance, because if nervous tissue is once destroyed it cannot be regenerated. The streptococcicidal effect of hydrochloric acid should prevent the nervous disease from progressing further, while liver cures the early pernicious anaemia, as shown by the restoration of the red cells to their normal size.

SUMMARY.

Pernicious anaemia has not yet been defined; it is a syndrome of about a dozen symptoms, none of which is present of necessity, unless nowadays we except enlargement of the red cells. In the appended table I have set down these symptoms in double columns, and it is evident that those of the early stage of pernicious anaemia are so different from those of the later stages that it is absurd and misleading to include them in the same syndrome, and a separate name is required. It is pernicious anaemia before it has become pernicious; hence the name "pre-pernicious anaemia."

If, as I believe, it can be accepted that enlargement of the red cells is an invariable feature peculiar to pernicious anaemia in all its active stages, then the two dissimilar syndromes (pernicious and pre-pernicious anaemia) can be included under a single definable disease called megalocytic anaemia. But this definition can hardly be adopted until a ready means of measuring the average size of red cells is available to the clinician. I believe the halometer supplies this want.

Abstracts of ten cases which bore out the opinions expressed above were submitted with this paper, but space does not permit of the publication of more than the two case reports appended.

Table showing the Distinguishing Symptoms of Pernicious and Pre-pernicious Anaemia (not Absolute).

Symptoms.	Pernicious Anaemia.	Pre-pernicious Anaemia.
Nine surface differential symptoms:		
Complexion	Pale or lemon	Commonly florid
Haemolysis	Present	Usually absent
Poikilocytosis	Present	Absent
Anisocytosis	Conspicuous	Inconspicuous
Polychromasia	Present	Absent
Nucleated red cells	Often present	Absent
Colour index...	High	May be normal or low
Blood platelets	Absent	Present
Body weight	Well retained	Reduced initially
Six basic symptoms in common:		
Enlarged red cells	Present	Present
Achlorhydria	Present	Present
Tiredness	Present	Present
Glossitis and oral sepsis	Often present	Often present
Spinal cord changes	Often present	Often present
Response to liver	Marked	Marked

LIGATURE OF INNOMINATE AND COMMON CAROTID ARTERIES FOR SUB-CLAVIAN ANEURYSM.

BY

C. L. GRANVILLE CHAPMAN, F.R.C.S.I.,

SURGEON, GRIMSBY AND DISTRICT HOSPITAL.

THE case reported below is of interest as a sequel to a fractured clavicle and because of its comparative rarity.

A fisherman, aged 33, on August 19th, 1928, was struck on the right side of the chest at sea with a messenger hook, and reached hospital next day. He was much bruised over the whole of the right chest, and *x*-ray examination showed a very oblique fracture of the right clavicle at the junction of the inner and middle thirds. He developed pneumonia, and was discharged on September 7th. Three weeks after leaving hospital he noticed a swelling above the right clavicle; in seven to ten days the swelling rapidly increased in size, and he was readmitted to hospital on October 5th.

Previous History.—He had trench fever in 1914, but in 1919 was discharged as A1.

On readmission he was very pale and looked ill; the temperature was intermittent. The mouth was extremely foul, full of septic roots, and pyorrhoea was well marked. He had a large pulsating tumour extending from above the clavicle as high up in the neck

CASE I (from Dr. Sproulle).

A florid, well-nourished unmarried woman, aged 25, complained of loss of strength, appetite, and weight for one year. She had a sore tongue last year. The gums tasted nasty when sucked; her teeth were good. Examination was negative. The red cells numbered 3,200,000 per c.mm.; haemoglobin 90 per cent.; colour index 1.2. The red cells were irregular in size, but not in shape; there were no platelets. The blood halo was bright and sharp, but too small (4.1 degrees). Her weight was 8 st. 3 lb. At her first visit, in June, 1928, a diagnosis of early pernicious anaemia was made, and she was given liver and hydrochloric acid. In two months she felt quite well and resumed her work and tennis. She stopped treatment and did not report herself again, though solemnly warned that she must do so. After six months (December, 1928) I found her address and insisted on a fractional test meal, which duly showed achlorhydria. She had started to lose weight—6 lb. in three weeks—presumably the beginning of a relapse. The van den Bergh test was normal. The red cells numbered 4,800,000 per c.mm.; haemoglobin 80 per cent.; colour index 0.8. Blood halo 4.4 degrees; hence the red cells were improved in size, but not yet normal (4.6 degrees), owing to stopped treatment. She hated eating liver, so she minced it raw, rubbed it through a fine sieve, and mixed it with a cup of weak warm bovril seasoned with pepper and salt. This she drank three times a day with her eyes shut.

On April 23rd, 1929, she was very well and had gained 24 lb. in the nine months' treatment. Haemoglobin 100 per cent.; a few platelets. She can walk five miles. Blood halo 4.78 degrees (originally 4.1 degrees).

CASE II (from Dr. Cameron).

This patient, seen in November, 1928, was a well-nourished well-coloured man of 45. He complained only of tingling in the feet and finger-tips for a month. The legs felt a little numb and stiff; there was no anaesthesia. The reflexes were normal. Blood halo 4.2 degrees, sharp and bright. A diagnosis of subacute combined degeneration and pernicious anaemia (early) was made. This was confirmed by finding achlorhydria, and colour index 1.1, red cells 3,000,000 per c.mm., haemoglobin 65 per cent., white cells 9,600 per c.mm., a few poikilocytes and microcytes (Dr. Adamson). When seen again, after six months on liver and hydrochloric acid, he felt very well, and his colour was better than ever before. The tingling was much less; none in the hands. Walks a mile. Sexual power had returned after nine months' absence. Haemoglobin 90 per cent. Blood halo 4.78 degrees (high normal).

as the cricoid and also below the clavicle; the sterno-mastoid muscle was displaced outwards. The radial pulse could not be felt. The left pupil was slightly dilated, and there was some proptosis. Pain was felt at the site of the tumour. An *x*-ray photograph showed a tumour occupying a big area in the upper chest, but on attempting to screen him he collapsed. The Wassermann reaction was negative.

As the tumour was growing so rapidly and appeared likely to burst, in spite of his septic condition it was decided to do an immediate operation on October 16th.

Operation.—The whole of the right arm was carefully bandaged with a thick layer of wool. An incision was made along the sterno-mastoid to join a transverse incision along the clavicle. The sac was extremely thin, but an attempt was made to dissect it down, when it was found to extend to the left side and under the left sterno-mastoid. The middle third of the clavicle was resected subperiosteally, and it was then seen that the tumour arose from the subclavian artery. The sac ruptured, and the bleeding was very severe; this was stopped by the finger used as a plug to close the opening. The common carotid was exposed and tied, and the vagus nerve demonstrated. There was no part of the subclavian artery which could be tied. Traction was now made upon the common carotid, the pleura pushed downwards, when the innominate artery was exposed. No great difficulty was met in passing the aneurysm needle, and the artery was tied securely with two ligatures of kangaroo tendon, side by side. This immediately stopped all haemorrhage. The sac was then removed as far as possible, and the adherent portion sewn over. The clavicle was replaced, the periosteum sewn over it and joined by kangaroo tendons.

The patient left the theatre in good condition. During the night and all the next two days the right side of the head was obviously colder than the left; capillary circulation in the hand was present the next day, and the arm kept warm and comfortable.

He ran an intermittent temperature and developed bedsores and some suppuration in the wound; the centre piece of the clavicle separated. His mouth gave a good deal of trouble, and the roots of all teeth were extracted. Later he developed an empyema on the right side; a rib was resected, and the condition healed in three weeks.

He was discharged from hospital on April 10th, rapidly gaining weight and looking well.

I have to thank my colleague Mr. Cecil Burnett for his ablo assistance, and Dr. A. Thomson, the house-surgeon, for skilful anaesthesia in a poor subject for a long operation.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

RENAL ABNORMALITY.

(*With Special Plate.*)

APART from the pathological condition found, the following case appears to be interesting as an example of a physical stigma of degeneration in a congenital mental defective.

The patient was a mentally deficient lad, aged 20. He was operated on for acuto appendicitis, and died, leaving a faecal fistula at the site of operation. A post-mortem examination was made, and the following are notes having bearing on the condition found.

Having failed to find the kidneys in their normal situation, it was decided to explore a pelvic tumour occupying a position in the mid-line below the fifth lumbar vertebra. This tumour was retroperitoneal and gave a doughy resistance on palpation. When the peritoneum was incised there was no difficulty in enucleating the tumour, but owing to a single attachment it could not yet be removed from the body. This attachment was traced downwards, and turned out to be a ureter. About two inches from the bladder this ureter gave off a branch from its left side, which, when it was traced upwards, was found to enter a scarcely developed left kidney which was lying against the much larger right kidney (see Special Plate, Fig. 1). The ureters therefore joined and had a common entry into the bladder. Both kidneys were now removed and examined macroscopically, microscopically, and bacteriologically.

Right Kidney (weight 238 grams).—Nodular elevations filled with pus were present on the surface. On being cut open (Fig. 2) the kidney was found to consist mainly of abscess cavities with very little normal kidney substance, and no macroscopic differentiation between cortex and medulla. The pus contained *B. coli communior* and *Strep. faecalis*. Sections showed some normal kidney substance, enormous leucocytic infiltration of the kidney, and a streptococcus; bacillary forms did not show up on section.

Left Kidney.—Except for its size and its weight, which was 17 grams, the condition of the left kidney was similar to that of the right.

The faecal fistula communicated with copious pus in the appendicular region. There did not appear to be any direct connexion between this and the kidneys.

Didsbury, Manchester. C. R. NUNAN, M.B., D.P.H.

INTRAVENOUS ANTITOXIN IN AN OUTBREAK OF SCARLET FEVER IN A PUBLIC SCHOOL.

SCARLET fever of a severe semi-septic type broke out among the boys of a public school in February, 1929. The first nine cases were treated by ordinary expectant methods and without antitoxin. The course of the disease in these gave rise to much anxiety, and complications were frequent, as noted in the table below.

Then occurred the worst case of all, in a boy aged 13, who, when seen by me about the seventh day of the disease, had already a severely ulcerated throat, enlarged and tender cervical glands, double acute suppurative otitis media, and acute mastoid suppuration on one side. He was given 10 c.cm. of scarlatinal antitoxin intravenously, unfortunately without effect at this stage. The sepsis developed into pyaemia with multiple purulent arthritis, involving incisions into the hip-joint, the elbow-joint, and both ankle-joints, and the double mastoid operation. The serum was given too late in this instance, and the dose was too low for such a severe case.

The subsequent patients, sixteen in number, were treated early in the acute stage with antitoxin intravenously, according to the technique which I have previously described.[1] In these sixteen cases the acute stage, though apparently of the same sharp type as the others, was arrested within twelve to twenty-four hours of the injection. Further, no desquamation occurred; the complications were limited to mild adenitis in one patient, who received antitoxin on the fourth day of disease, and one simple hordeolum. All the sixteen patients were allowed up within a week, and were discharged from isolation in about a fortnight's time. All were boys between the ages of 12 and 18, except for one master aged 49. All received the injections within the first four days of their disease, generally on the second or third day.

No ill effects were noted from the serum administration, although one boy had a moderately severe rigor, and two had hyperpyrexia for a few hours after the injection. In one case intravenous serum appeared to be contraindicated owing to a history of hay fever. In this case an intradermal test injection of 1 in 10 dilution of the serum was performed, and it did not produce any reaction. Accordingly the usual dose, 10 c.cm. of serum, was injected intravenously, and no ill effect was noted.

The following table gives particulars of the complications noted in this interesting series.

SCARLET FEVER COMPLICATIONS.

Nine Cases not treated with Antitoxin.	
Suppurative otitis media with persistent otorrhoea...	2
Non-suppurative otitis media	2
Albuminuria or nephritis about third week	7
Empyema of maxillary antrum and frontal sinus ...	1
Dacryocystitis	1
Pneumonia	1
Jaundice	1
Adenitis	1
Nasal discharge	1
Desquamation	7
Sixteen Cases treated with Intravenous Antitoxin.	
Adenitis	6
Hordeolum	9

The only case omitted from the table is the one previously noted of severe pyaemia, in which the serum was given too late to be effective.

The injections, with the exception of the first two, were made by Dr. Hubert L. Ellison, to whom I am indebted for detailed information as to the course of the outbreak.

H. STANLEY BANKS, M.D.Glas., D.P.H.,
Medical Superintendent, Isolation Hospital and Sanatorium, Leicester.

ANTIMONY TREATMENT OF ACNE ROSACEA.

HAVING recently demonstrated to my own satisfaction, and as far as is possible with the limited number of cases at my disposal, the great benefit to be derived from the use of antimony in chronic and subacute skin conditions, I record the following clinical details.

A woman, aged 36, came to me on March 18th, suffering from acne rosacea. She had a patch on each cheek about two inches square, much thickened and indurated, and very congested and red over the surface, with numerous indurated papules, especially along the lower edge. She gave a history of having been treated at a London skin hospital for six months without much improvement, and thinking that most of the usual remedies would have been tried, I decided to put her on antimony tartrate 1/16 grain in half an ounce of water three times a day after meals. The following lotion was applied night and morning:

Sulph. praecip. Pulv. zinci oxidi Mag. carb. levis	} ...	...	...	...	āā	2 drachms
Glycerini	...	...	...	...	...	1 oz.
Aquae	...	...	...	...	ad	8 oz.

There was a very marked improvement in a week, which steadily went on till April 22nd, when the whole of the skin of both cheeks was quite clear, except for one small papule low down on the left side, only noticeable on careful examination. On April 29th the skin was all clear and treatment was discontinued.

Believing that the above result was due to the use of antimony, I have since tried it on two cases of furunculosis, one of which was affecting the hair roots of the back of the neck and causing a condition similar to sycosis; in both cases the result was markedly and definitely beneficial.

A man came to see me on January 15th with several boils on his neck, combined with fairly severe seborrhoea of the scalp. At first he was treated with lotio plumbi and collosol manganese injections every four days, combined with active treatment for the seborrhoea. The improvement, if any, was very transient, and soon he began to lose one after another of his finger-nails with a kind of subacute paronychia ungualis. On February 18th there appeared to be no improvement, and he was put on biniodide lotion 1 in 2,000 and collosol manganese every two days. There was a slight improvement by March 27th, when I decided to try antimony tartrate 1/16 grain thrice daily. On April 3rd there was a definite improvement; on April 8th he was better still, all the boils and papules having quietened down, the fingers having improved, and no fresh point of inflammation having developed. On April 24th, not having seen him again, I wrote asking how he was, and he 'phoned to say he was going on famously. I have not seen him since.

I have also had good results in cases of ulcerated legs when the surrounding skin was thickened, red, and indurated; the administration of antimony caused an all-round improvement, and a more rapid healing of the sores.

Catford, S.E. L. W. BAIN.

Reports of Societies.

SOME DISEASES OF THE JEWISH RACE.

A SYMPOSIUM on some diseases of the Jewish race was held by the London Jewish Hospital Medical Society on June 13th. Dr. A. GOODMAN LEVY was in the chair.

Sir HUMPHRY ROLLESTON, in opening the discussion, said that diseases had been described as racial diseases of the Jews for no better reason than that the first recorded cases happened to have occurred among Jews. Such was the case with the condition known as dystonia musculorum deformans, also known as Oppenheim's disease. But there were diseases which, if they did not appear exclusively among Jews, were said to occur more frequently among them; thrombo-angiitis obliterans was a case in point. It had recently been suggested that this disease was on the decrease among Jews and on the increase among Gentiles. It was possible that the stress laid on the racial nature of this affection had led to its being overlooked when it occurred among Gentiles. According to Telford and Stopford the alleged racial character of this disease was the result of a "topographical" accident. A different course for the disease in Jews and Gentiles respectively had been claimed: it was said that its course in Jews was earlier and more severe; but the opposite view had also been advanced. On the question of amaurotic familial idiocy he pointed out that there were a series of allied conditions of which amaurotic familial idiocy and retinitis pigmentosa were the extremes, the first occurring early in life among Jews and the latter coming on much later in the case of both Jews and non-Jews. Both obesity and diabetes were relatively common in Jews, and it had been suggested by Joslin that Jews got diabetes because they were fat, and they were fat because of dietetic excess. But it must be remembered that Gaucher's and Niemann's diseases, which were disturbances of fat metabolism, were probably more frequent among Jews. Acromegaly had also been said to be more common among Jews, and anterior lobe pituitarism as a feature of the Jewish race was compatible with Keith's contention that the special effects of pituitary activity were best seen in the Caucasian type. That Gaucher's disease was regarded as being specially common among Jews was probably due to the accident that it was extensively investigated at the Mount Sinai Hospital. Niemann's disease, which was probably a more severe type of Gaucher's disease, appeared to be more frequent among them—if one could argue from the fifteen cases of this disease which had been reported. It probably exemplified the rule suggested by the relationship of amaurotic familial idiocy and retinitis pigmentosa—namely, that in the Jewish race there was a constitutional factor which determinated an earlier onset and a more severe form of certain diseases. On the incidence of cancer, the recent work of Sourasky had shown that whilst the total cancer mortality among Jews corresponded fairly with that of the countries in which they lived, there were some differences in the distribution of these growths, though these were probably due to the Jewish mode of life rather than to a racial factor. Tuberculosis had been regarded as rare among members of this race, but according to Feldman and others there was a great difference in their mortality and morbidity rates. Jews appeared to have a definite resistance to tuberculous infection, which was perhaps partly to be explained by their sobriety as a race. There seemed to be no special predilection for skin diseases among Jews.

Mr. A. H. LEVY, speaking of amaurotic familial idiocy, pointed out that it was wrong to regard the disease as a specifically Jewish one. Well-authenticated cases in non-Jewish infants were on record. Two such cases had been reported from London, one by Mr. Leslie Paton and the other by the speaker. The etiology of the disease was most puzzling; consanguinity and mental instability in the family of one of the parents had been blamed. Very little definite was known beyond the fact that the disease was familial in more senses than one. It appeared from a recent genealogy that the disease might establish extensive ramifications in a family, appearing in the offspring of a normal sister of victims of this affection. Another characteristic was that the disease might occur in only a single member of a family. The speaker had seen a case where one of twins had died of the disease, whilst the other showed no signs of it. The disease was not present at birth; it appeared at about the age of 3 months, and steadily progressed towards a fatal termination, usually by the age of 2. When fully developed Sach's symptom-tetrad was present: the typical macular appearance—a cherry-red spot surrounded by an area of milky haziness—blindness, idiocy, and paralysis. Pathologically the disease was definitely a degeneration of ganglion cells, not only of the retina but of the nervous system throughout, even involving the sympathetic. The appearance of the retina was striking: it was normal except for the complete absence of normal ganglion cells. From the racial point of view there was also some interest in juvenile and in adolescent cerebro-macular degeneration, diseases which were generally regarded as being allied to amaurotic familial idiocy. In the speaker's opinion the conditions were not at all allied. The juvenile and the adolescent affections had no predilections for Jews, and should not be regarded as later and milder forms of the infantile disease; the pathology appeared to be quite different, the first group being in all probability inflammatory and the infantile form degenerative. Mr. Levy also touched on the question of the alleged greater frequency of glaucoma among Jews, which he could not substantiate from his experience, and on the incidence of cataract, which was

probably not disappearing so rapidly in Jews as in the general population.

Mr. M. SOURASKY, speaking on cancer among Jews, said that the fact which emerged from a recent investigation was that Jews were neither immune to cancer nor specially prone to it. The statistics of six European capitals with large Jewish populations had been scrutinized, and in each of them the incidence of cancer among Jews followed closely that obtaining among their neighbours. On the whole, there was a closer relationship between the Jews and non-Jews of any particular city than between the Jews of different cities. That was to say, Jews did not show a specific racial incidence of cancer, but one subject to geographical variations. Jews and non-Jews showed, however, differences in the incidence of cancer in the various organs. Among Jews, cancer of the generative organs and of the mouth seemed to be rarer, and that of the gastro-intestinal tract commoner, than among non-Jews. There were, however, etiological factors operating in the Jewish community capable of explaining these differences without assuming the operation of a problematical racial factor—immunity or predisposition, as the case may be. Thus the well-known association of cancer of the tongue with chronic inflammation of this organ, which was so often of syphilitic origin, adequately explained the low incidence of cancer of the tongue in Jews, as syphilis was decidedly less common among them than among non-Jews. Not a single case of penile cancer has been recorded for Jews, whilst the disease accounted for about 1 to 2 per cent. of all cancer deaths among non-Jewish males. Yet in this case of apparent immunity the racial factor could not be invoked; it was also observed among the conglomeration of races who practised Mohammedanism. Most authorities accepted circumcision as the explanation. The incidence of cancer of the breast in Jewish women varied in different cities, being sometimes lower, sometimes a little higher, than that for the rest of the population. These differences could be accounted for by the established variations seen in different social groups. A similar explanation was advanced for the fact that in London the incidence among the poor Jews was lower than that among the wealthy. It was pointed out that among the richer Jews there were more unmarried women, the marriages were later, and the birth rate was lower, all factors favouring breast cancer. The remarkably low incidence of uterine cancer (one-third to one-half the number occurring in the rest of the population) might be attributable to the observance of the Mosaic system of hygiene, but the problem required further investigation. It was interesting to note that this form of cancer appeared to be rising in the Jewish community. Turning to the problem of the higher frequency of gastro-intestinal cancer in Jews, neither established nor possible etiological factors could be adduced as an explanation. The general tendency to attribute discrepancies observed in other forms of cancer to environmental influences would render a similar explanation of the higher incidence of gastro-intestinal cancer more feasible than one based on racial character. The well-known tendency of Jews towards metabolic disturbances—for example, obesity and diabetes—was worth remembering in this connexion.

Dr. J. BURNFORD remarked upon the extreme rarity of any specifically racial diseases, whether of Jews or of other races. The topography of disease was not so much a question of racial predisposition and immunity as of environment. Tropical diseases were tropical in the geographical and not in the racial sense. Theoretically speaking, there was a better case for racial immunity than for predisposition. Natural selection was more likely to produce a group of people resistant to certain affections than one which was specially prone to them. It was a remarkable fact that only one disease seemed to stand out as being specifically Jewish—amaurotic familial idiocy; but even this specificity was not absolute. Statistics from a hospital in the East End of London could legitimately be used to prove the frequency of certain diseases among Jews. It was generally assumed that diabetes was very common amongst Jews; in the speaker's experience this had not been very noticeable. Practice at the London Jewish Hospital did not involve treating more cases of diabetic coma than practice in a dominantly non-Jewish hospital. On the contrary, he had met with far more severe cases of diabetes and more cases of coma at hospitals where but few Jewish patients were seen. It was perhaps true that glycosuria was more frequent amongst the well-fed and under-exercised Jews, but that might equally well apply to any people. Environment was rapidly changing in the case of Jews, and in all probability less would be heard of "Jewish diseases" as time went on.

Dr. W. M. FELDMAN, speaking on tuberculosis, said that the mortality rate from tuberculosis was lower among Jews than among Gentiles, which was to be explained by the fact that the disease was less fatal among them. This could be seen from the greater number of Jews who responded favourably to treatment. Though the fact that the disease was milder in Jews was well established, the explanation was by no means clear. The dietary laws had been held responsible for this happy state, but the disease appeared to be as prevalent among the observant as among the non-observant. Natural selection operating through a heavy mortality among the Jews of earlier centuries had also been called in; but this process did not seem to have weeded out the narrow chests among the Jews. In the speaker's opinion the explanation was probably that Jews acquired immunity from frequent exposure during childhood to mild doses of tuberculosis, being especially prone to this on account of the greater frequency of the disease among Jews, its milder character, and the greater degree of overcrowding. The greater care Jews bestowed on their infants and their greater sobriety probably also counted.

Mr. A. SOURASKY, speaking of visual defects, said that in a recent investigation 1,649 Jewish boys were examined as regards eyesight in a group of Jewish evening schools in the East End of London, and 600 non-Jewish boys in London County Council schools in the same district. The tests showed that the percentage of Jewish boys with visual defect was 43.2, as against only 21.7 of the non-Jewish. The incidence of defective vision in Jewish boys was thus about double that in non-Jewish. In this respect the figures corresponded with the findings of previous inquiries. But the conclusion often drawn that the extra hours of evening study in Jewish classes were responsible was found to be unjustified, since a further analysis of the data obtained proved that the incidence of the defect in Jewish boys did not increase with the school age and was already present to the same extent among school entrants. Thus children at the age of 5 and 6, who had not yet reached school age and therefore could not be influenced by school life, showed a similar amount of visual defect to that found at the school leaving age, between 12 and 14. It would therefore appear that the preponderance of the defect among Jewish children was of a structural origin and not determined or brought out by an excessive amount of close work which had to be done by Jewish boys in evening schools. Defective vision was then studied with reference to the type of error involved, and it was found on an investigation of defects seen among 516 Jewish and 892 non-Jewish children that the proportion of long-sighted and short-sighted was such as to suggest that among Jewish children short sight was twice as frequent as among non-Jewish. At the same time, the tests led to the detection of very striking differences in the kind of long sight observed among Jewish children. One type, "low hypermetropia," was found to be more common in Jewish children than the other forms of long sight, and this was not the case with non-Jewish children. The predisposition to short sight in Jewish children and the greater incidence among Jews would appear to be the concomitant of the fact that the anthropological characteristics of the eyes of Jews were such as to leave little margin between the normal and the myopic. Hence slight disturbances were more likely to result in myopia in Jewish children than in the non-Jewish.

In the subsequent discussion Dr. F. PARKES WEBER said that in his opinion thrombo-angiitis obliterans was a disease with an economic basis rather than a racial one. Dr. BERNARD MYERS held that many Jewish characteristics could be explained on the basis of endocrine disturbances.

Reviews.

PRIMARY CANCER OF THE LUNG.

DR. HUGUENIN'S book on primary cancer of the lung[1] appears at a time when, for two reasons, the subject is attracting special attention. In the first place, it is now believed that cancer of the lung is of more frequent occurrence than formerly; and, secondly, excision of the growth has been proved in recent years to be a perfectly feasible operation in suitable cases. As regards frequency, Huguenin quotes statistics from Basle, Leipzig, Berlin, Hamburg, Vienna, and Zürich, and in every instance a considerable increase in its occurrence is recorded in recent years. The disease, however, is rare; in 8,056 necropsies in Jena between 1910 and 1924 there were 987 cases of cancer, and of these 41, or 4.2 per cent., were primary carcinomas of the lung. Lubarsch gives approximately the same percentage for the whole of Germany. With regard to the cause of the disease, its frequency among the miners of Schneeberg is strong evidence of the influence of the inhalation of irritating substances. It has been known for centuries that the miners were extremely liable to pulmonary disease, and in 1879 Härting and Hesse proved that it was due to malignant growth. The matter was thoroughly investigated by Rostoski and Saupe in 1922; 154 miners were examined, 21 died during the period of investigation, and of these no fewer than 13 had malignant tumour of the lung. The disease in Schneeberg appears to depend on some cause peculiar to that particular mining district: as regards the general increase, Huguenin discusses the question whether modern innovations, such as the extensive use of petrol, may not be regarded as responsible for it. The disease is stated to affect men much more frequently than women, a fact which has been attributed (erroneously, according to the author) to the greater exposure of men to sources of pulmonary irritation. To the subject of operative treatment the author refers but briefly; none of the 43 cases of which he gives full clinical details were operated upon, and he states that excision of the growth has not yet been attempted in France.

The book is chiefly concerned with the macroscopic and microscopic anatomy of the disease, and with its clinical manifestations. Careful descriptions are given of the various forms of the growth and of their histological characters, and these are illustrated by many excellent plates. The chapters on the symptomatology and diagnosis are equally good. The author has aimed at producing an anatomico-clinical picture of the disease, and in this he has been eminently successful.

DISEASE IN THE TROPICS.

To those who are familiar with the previous editions of STITT'S *Tropical Diseases*[2] the new edition will cause surprise, for the volume, so attractive on account of its modest dimensions, has now grown into a comprehensive treatise of over 900 pages. On this account the book is in many respects an entirely new one, though much of the matter from the smaller fourth edition has been incorporated. While the greater part of the book is devoted to those diseases which have come to be regarded as peculiar to or specially prevalent in the tropics, others such as influenza, tuberculosis, scarlet fever, etc., receive attention, and their importance to the practitioner in the tropics is emphasized. The book is thus more a treatise on general medicine and surgery as practised in the tropics than a textbook of so-called tropical diseases. This, however, does not detract from its usefulness; on the contrary, its value to the medical man far removed from the resources of civilization is thereby greatly increased. He will be prevented from falling into the error of concluding that the diseases with which he became familiar in temperate climates do not occur in tropical lands.

In its general arrangement and classification of diseases the text follows the usual lines, the various sections dealing in sequence with diseases caused by protozoa, with which the spirochaetes are included, bacteria, filterable viruses and Rickettsias, defects in nutrition, fungi and injurious plants, animal parasites including helminths, arthropods, fish, and snakes, while one section is devoted to diseases not satisfactorily grouped in the foregoing, such as heat-stroke, tropical ulcer, granuloma venereum, climatic bubo and ainhum, and another, the eighth, to problems of medical and surgical practice in the tropics. In all these sections the diseases are carefully and fully described and are thoroughly up to date. It is perhaps too much to have expected that the new *Filaria malayi* should have been mentioned, but reference might have been made to the doubts that have arisen as to the validity of the train of symptoms which have been attributed to infections with *Schizotrypanum cruzi* in South America. The part of the book occupied by the sections just referred to is in large clear type and is fully illustrated. It is followed by an appendix of almost 250 pages in small type. In this there are four sections—namely, index to clinical diagnosis, laboratory procedures, index to essential laboratory procedures, and tropical hygiene. The first section gives a very useful analysis of the main symptoms and signs described in the first part of the book. In that devoted to laboratory procedures almost every conceivable process is dealt with, and we imagine that laboratory workers in the tropics will make constant reference to it. The index to laboratory procedures gives at a glance the laboratory methods applicable to each disease for purposes of diagnosis, though we note a curious omission in the absence of reference to sleeping sickness. Section iv of the appendix deals with tropical hygiene, and this in itself is a very excellent outline of the subject.

The book concludes with an index which strikes one as relatively short for the size of the volume. Whether it will prove to be sufficient can only be determined by repeated reference. In matters of nomenclature of micro-organisms the American standard is adopted, but other names are inserted where this may lead to ambiguity. Reviewing the book as a whole, the only conclusion possible is that it is a remarkably good one, and those who decide to use it can do so with every confidence.

HISTORY OF PSYCHOLOGY.

PSYCHOLOGY has had to struggle hard for differentiation as a separate branch of study, and even to-day recognition of its individuality is not yet assured. At one time a mere appendage of philosophy, in the mid-nineteenth century it came to acquire the status of an experimental science; since then, however, it has been in danger of losing its identity in the larger disciplines of physiology and biology. Its history is the history of numerous philosophies, of the many kindred sciences, and of its own specific growth.

In tracing this development in *An Historical Introduction to Modern Psychology*,[3] Dr. GARDNER MURPHY has fulfilled admirably a most difficult task. The enormous and ever-increasing output of literature on all manner of psychological subjects makes the task of selection a peculiarly onerous one. The author admits that the fact of having to select from so great a mass of material, and of having to emphasize certain aspects of it, precludes the possibility of making, as he would have liked, an entirely impersonal and objective record of his subject. There is no cause for regret. No purely objective record could be as successful as Dr. Gardner Murphy's presentation of the history which bears evidence everywhere of a judicious choice of material and of such emphasis as is free from any prepossession. With regard to the space he allocates to the contributions of each era, the author likens his plan to Mercator's Projection. The nearer a decade approaches the present day, the more the space devoted to it. It is

[1] *Le Cancer Primitif du Poumon.* Par René Huguenin. Préface du Professeur G. Roussy. Paris: Masson et Cie. (6½ × 10. pp. iv + 330; 55 figures, 1 plate. 50 fr. sans majoration.)

[2] *The Diagnostics and Treatment of Tropical Diseases.* By E. R. Stitt, A.B., Phar., M.D., Sc.D., LL.D. Fifth edition, revised. London: H. K. Lewis and Co., Ltd. 1929. (Med. 8vo, pp. xx + 918; 243 figures. 31s. 6d. net.)

[3] *An Historical Introduction to Modern Psychology.* By Gardner Murphy, Ph.D. With a supplement by Heinrich Kluver, Ph.D. The International Library of Psychology, Philosophy, and Scientific Method. London: Kegan Paul, Trench, Trübner and Co., Ltd. (Demy 8vo, pp. xvii + 470. 21s. net.)

a plan which works very well and affords an adequate perspective. In Part I separate chapters are devoted to the psychology of the seventeenth, the eighteenth, and the early nineteenth centuries; and these are prefaced by a brief account of the intellectual background of seventeenth-century psychology. The contributions made to psychology by Hobbes, Locke, Berkeley, Hume, and Kant are skilfully summarized. The teaching of Cabanis and his doctrine of nervous system "levels" is of special interest to all who are familiar with the work of Hughlings Jackson a century later. In the early nineteenth century the Herbartian psychology was born. Herbart's theories have a curiously modern ring. His three modes of relationship of experience with consciousness bear a striking resemblance to the "conscious," "foreconscious," and "unconscious" of Freud; but though Herbart's psychology was a dynamic one, his theory of opposing ideas meant for him ideas in logical opposition, which does not presume, as the author points out, that they necessarily lead to divergent lines of conduct.

The second part of the work is devoted principally to the study of the growth of experimental psychology and of physiological psychology before and in the age of Wundt. There is a particularly interesting account of Fechner, both as the founder of the science of psychophysics and as a mystic. The contributions made to psychological thought by Pinel and later by Charcot are examined. In the larger portion of this book, which is devoted to contemporary psychology, Dr. Gardner Murphy maintains the strict continuity of thought which is so admirable a feature of his writing. He shows how experimental methods have been applied to the more complex problems of thinking and willing, and he traces the growth of the numerous subdivisions of the science of psychology. It would serve no useful purpose to set forth a summary of the contents of this part. Suffice it to say that the author is equally at home in dealing with the psycho-analytic problems of narcissism and regression as with the tenets of behaviourism. A study of contemporary German psychology by Dr. Heinrich Klüver forms a valuable supplement.

PAEDIATRICS FOR THE GENERAL PRACTITIONER.

DESPITE the growth of paediatrics as a specialty, it is the family doctor who, rightly, is first called upon to advise when children become ill, and it is important in the scientific study of children's diseases that the needs of the general practitioner should be kept in mind. Professor H. M. MCCLANAHAN has written an admirable book, entitled *Pediatrics for the General Practitioner*,[4] in which the practical aspect has been kept uppermost, while at the same time the scientific side is presented in a well-balanced manner. In just under 600 pages of clear print, well illustrated, the whole subject of diseases of children is set out, including chapters on the infectious disorders, diseases of the eye, ear, nose, and throat, tropical diseases, and diseases of the skin. The volume opens with a good chapter on the normal human infant, and the stages of normal development, physical and mental, are well traced, serving as a background for the rest of the book. Birth injuries and congenital malformations are next described, and thereafter the book follows the usual lines as far as chapter headings go. The author's description of symptoms and signs is clear throughout, and it will be noticed that again and again the most important part of his description of a disease is concerned with treatment. Rare disorders are mentioned without being given undue prominence, and a bibliography at the end of every chapter sums up the latest and the most important literature on the subject without attempting to be too detailed or complete. The author has recently visited this country, and in many parts of the book he acknowledges information picked up in his travels, a courtesy all too frequently forgotten. He has also read widely and digested a great deal of literature. This is a volume which is admirably suited to the needs of the practitioner.

[4] *Pediatrics for the General Practitioner.* By Harry Monroe McClanahan, A.M., M.D. London: J. B. Lippincott Company. 1929. (Med. 8vo, pp. xi + 606; 220 figures. 25s. net.)

MOVEMENTS OF PLANTS.

No more beautiful series of researches has ever been carried out than those recorded by Sir JAGADIS CHUNDER BOSE in his work on the *Motor Mechanism of Plants*.[5] Certain definite movements in response to stimulation have long been known in connexion with particular plant structures, such as the anthers of Berberis; but until Bose interested himself in the subject it was unsuspected that motility could be considered as a universal characteristic of plants, or that they possessed motor organs comparable to muscles, and conducting tissue comparable to the Purkinje fibres of the heart. The movements of the protoplasm within the cell membrane are well known to every student of botany, but it remained for Bose to show that under normal environmental conditions the cell exhibits a liquid tumescence or tonus, and that stimulation causes a depletion of liquid with a resulting diminution in the size of the cell—that is to say, a contraction. By means of experimental apparatus of extraordinary delicacy, devised by himself, Bose has succeeded in measuring the amount of this contraction in the individual cell, and has shown it to be about one thirty-millionth of an inch under feeble stimulation. Cells specially endowed with contractility are segregated into definite masses or tracts, somewhat analogous to muscles, subserving definite ends such as the movement of a leaf or the propulsion of sap; and they may be recognized microscopically by definite staining reactions. Bose has taken graphic records of the curve of contraction, with its latent or refractory period, its rapid rise and more gradual fall, and its associated electronegative variation, as in animal muscle. He finds that the response is of the "all-or-none" type exhibited by heart muscle, and that the effect of physical and chemical agents and poisons on the curve corresponds to that observed in animal tissue. Of particular interest are the observations on rhythmical and peristaltic movements. Good examples are afforded by Desmodium and Biophytum. The small lateral segments of the trifoliate leaf of the former plant exhibit automatic rhythmical contractions, each contraction being completed in about a hundred seconds; of the latter plant, when in a condition of good tonus, it is said that a mere touch of one of its leaves may set all its leaflets quivering, throwing them, it would seem, into clonic spasm. The explanation of the automatic rhythmical contractions is that usually accepted in the case of muscle—namely, the action of a continuous external or internal stimulus on a contractile tissue exhibiting a refractory period. Bose has made the interesting discovery of a connecting link between the single contraction or twitch and automatic rhythmical contractions. He has observed that while a single weak stimulus will provoke a single contraction, a single stronger stimulus will produce a series of several contractions; thus it appears that the energy evoked by the stimulus is not exhausted in the initial contraction, but is gradually expended in a short series of automatic rhythmical contractions. Special interest will be taken in Bose's account of the mechanism concerned in the propulsion of the sap; but the whole book will be found to be a veritable romance of plant life.

NOTES ON BOOKS.

ALL who are familiar with the French literature of tropical medicine know and esteem the name of Sergent. In one issue of *Archives de l'Institut Pasteur d'Algérie* (1928, tome vi, Nos. 2-3), Edmund and Etienne Sergent have gathered together the experience of twenty years' work for the suppression of malaria in Algeria. There is, therefore, nothing very new in the volume. It is divided into two parts: the first deals with the story of the efforts which have been made and with the lessons learnt from them; the second part is an annotated bibliography of the published work dealing with the subject under notice, largely, if not entirely, the publications of the Sergents, but the names of the authors are not stated against the papers quoted. All the familiar means of prophylaxis are dealt with, and a point is made of the fact that, in circumstances such as those of Algeria, it is easier to rid the population of the parasite than to clear the country of the vector. Curiously, though it is stated that the relative frequency of the

[5] *The Motor Mechanism of Plants.* By Sir Jagadis Chunder Bose, M.A., D.Sc., LL.D., F.R.S. London: Longmans, Green and Co. (Demy 8vo, pp. xxv + 429; 242 figures. 21s. net.)

species of plasmodium is in the order vivax, praecox, malariae, the proportionate incidence of each is not stated for Algeria, but is given for Corsica. The volume is profusely illustrated and carefully indexed.

In the Antimalaria Campaign in Corsica[6] Dr. J. SAUTET gives us one of the studies of purely local conditions which are becoming increasingly common with the spread of the realization that malaria is entirely a local problem. These detailed studies are probably of the greater local value the smaller the area surveyed, but it must be admitted that their general interest is correspondingly limited. It is by no means certain, for example, that the methods proving satisfactory in Corsican experience will be as effective elsewhere. It is the more regrettable, therefore, that some of the less immediately applicable lines of study which the author followed are not more fully reported. No doubt it is very important for Corsica that local incidence of malaria in plains, valleys, foothills, and mountains should be accurately studied, and that the peculiar habits of the local people should be considered; but Corsican people and Corsican conditions are not encountered over any great area of the world, while the several species of mosquito carrying malaria in Corsica fulfil the same function in many lands. One could wish, therefore, that in publishing his study of the conditions under which malaria carriers live and breed the author had given particulars of the species with which he was dealing. It seems reasonable to suppose that the same limits of salinity of water will prove objectionable or attractive to *Anopheles maculipennis* (or other species) in *any* country, and we know that different species of anopheles are *not* alike in their preferences in such matters. The matter is not at all advanced by observations that larvae of some sort or another, unstated, were or were not found under such and such conditions. These criticisms do not detract from the book's interest and value as a study of the local problems of Corsica, and the lot of sanitarians going to work in out-of-the-way places would be greatly lightened if they could there find ready for them such studies as this of the problems confronting them.

The second volume (Bandwürmer–Dyspnoe) of the new German dictionary of practical medicine,[7] edited by Professors GEORG and FELIX KLEMPERER, has appeared soon after the first, which we noticed some months ago in this column. Among the forty articles which the second volume contains we may draw attention to those on Barlow's disease by Professor L. F. Meyer, biochemistry by Dr. R. Ahlenstiel, lead poisoning by Professor Benno Chajes, examination of the blood by Professor H. Hirschfeld, infantile diarrhoea and vomiting by Professor H. Finkelstein of Berlin, bronchial asthma by Professor P. Krause of Münster, diseases of the heart by Professor A. W. Meyer of Charlottenburg, cocainism by Professor H. W. Maier of Zürich, methods of intestinal examination by Professor G. Ganter of Rostock, intestinal obstruction by Professor von Haberer of Düsseldorf, diabetes mellitus by Professor E. Graefe of Würzburg, diathermy by Dr. F. Nagelschmidt of Berlin, and diphtheria by Professor R. Fischl of Prague. The text of the present volume, like that of its predecessor, is liberally interspersed with illustrations, plain and coloured.

In their essay on arterio-sclerosis of the lesser circulation[8] Drs. BENEDETTI and DE CASTRO point out that this condition was first described by Andral just a hundred years ago. They give a lengthy and elaborate description and discussion of the subject, detailing two new cases of their own and quoting forty-eight others from the literature. The diagnosis of pulmonary arterio-sclerosis is, very properly, described as very difficult; its treatment is no less unsatisfactory, unless, indeed, a syphilitic factor is present. The book may be recommended to pathologists and to those interested in the rarities of medicine.

Dr. LOUIS MOINSON in his little volume on glandular therapy[9] has aimed at writing a semi-popular account of this fascinating new chapter in medicine. The author expresses the hope that his volume may help the general public to grasp the outstanding facts of the science, and that even medical men may find his summary of the facts useful in refreshing their memory. "Indocti discant et ament meminisse periti." The book, which only contains 190 pages, gives a very readable account of the nature and functions of the endocrine organs, and finishes with two chapters on organotherapy, which are written in a restrained and critical spirit. One of the most interesting features of the book is that it gives the French view of the history of the development of endocrinology. Owing to the dominance of the German work of reference, there is a certain danger of forgetting how much this science owes to such pioneers as Claude Bernard, Brown-Séquard, and Gley.

In her little book on *Health Work in Soviet Russia*[10] Miss ANNA J. HAINES, an American nurse connected with the American Friends Service Committee, gives a description, which though sympathetic is by no means blindly partisan, of the activities of the People's Commissariat for the Protection of Health. A vivid picture is presented of the departments for the protection of motherhood and infancy, health work in the army and navy, protection of children's health, health work along routes of travel, as well as those for combating tuberculosis, venereal disease, and epidemics. An instructive chapter deals with the campaign against alcoholism, which, since the suspension of prohibition in 1925, appears to be increasing in the towns, though diminishing in the villages. There is also a chapter on medical education in Russia, which includes an account of the curriculum for nurses and midwives.

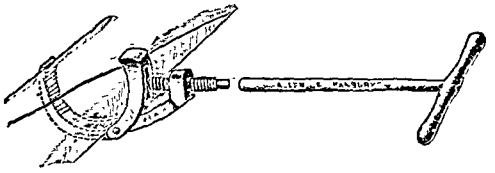
PREPARATIONS AND APPLIANCES.

A BONE-RETAINING CLAMP.

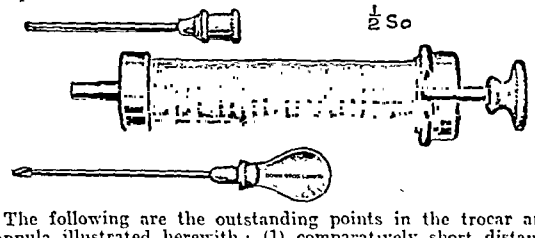
MR. ALAN H. TODD, M.S., F.R.C.S., writes: The instrument shown in the accompanying sketch is intended for use in operations upon oblique fractures of long bones, especially the femur and the humerus. The fragments are manipulated into perfect coaptation in the usual way with long bone-holding forceps, and the encircling clamp is then applied. If the fracture be of the long, oblique variety, two can be used, and retention is then perfect without the need of any other intervention by means of forceps, etc. This clamp has been devised to overcome some of the difficulties that are commonly met in the use of existing types. It is often



found that the handles of these clamps are very much in the way in the wound: either they have to be released in order to get the plate into position, or, as they can only be applied in one plane, they are not suitable for use in many cases of oblique fracture. The new clamp, the handle of which is detachable, occupies very little space in the wound, and it can be applied at almost any angle, according to the direction of the fracture. Even when one only can be used, it so far steadies the fragments that they can be held firmly in position by one assistant with very little effort. The clamp is made of stainless steel in two sizes by Allen and Hanburys, Ltd.

AN IMPROVED TROCAR AND CANNULA.

Dr. GEORGE JESSEL (consultant tuberculosis officer, Lancashire County Council) writes: In the aspiration of small abscesses—for example, cervical abscesses—and particularly in children, it is important to be able to carry this out as expeditiously as possible and with the minimum amount of inconvenience to the patient.



The following are the outstanding points in the trocar and cannula illustrated herewith: (1) comparatively short distance between point of trocar and the end of cannula; (2) close fitting of the end of cannula to the trocar, which is narrowed for the purpose, thus enabling the cannula to slip easily into the opening made in the skin; (3) convenient length and bore of cannula. The dimensions of the trocar are as follows: 2 in. long, No. 6 French catheter gauge.

The trocar and cannula have been made for me by Messrs. Down Brothers, Ltd., for use with a 10 c.cm. metal and glass syringe.

Nova et Vetera.

A CHEMIST'S BILL FOR THE SECOND DUKE OF BUCKINGHAM.

THIS fragment from the refuse heap of Time is interesting in many ways. First it bears out one of the epithets in Dryden's lines:

> "A man so various that he seem'd to be
> Not one, but all mankind's epitome;
> Stiff in opinions, always in the wrong,
> Was everything by starts, and nothing long;
> But in the course of one revolving moon
> Was chymist, fiddler, statesman, and buffoon."
> *Absalom and Achitophel*, Part 1, line 545.

A CHEMIST'S BILL FOR THE DUKE OF BUCKINGHAM.
His Grace the Duke of Buckinghams Bill.

(1667)		£ s. d.
	The bill which Mr. Wharton hath is ...	17=13=02
June 6.	2 Gall. Violls with stoppers double glasse ...	00=12=00
	1 Gall. Violl and stopper single glasse ...	00=05=00
	3 Pottle bottles and stoppers	00=09=00
	Porterage to Mr. Whartons	00=01=00
16.	1 half pint Retort and 1 pottle Retort ...	00=02=00
	6 ℥ Sal tartari	00=03=09
17.	2 lb Verdigreece	00=05=04
	1/2 lb Rhenish tartar	00=00=09
	6 pt Retorts	00=04=00
	6 1/2 pt Retorts	00=03=00
	6 Copping-glasses	00=02=00
	1 Nest of Crusibles and 1 Charne glasse ...	00=02=08
	1 qt Body, 1 vaporing glasse	00=02=00
	1/2 lb Salpeter	00=00=08
June 18.	Waterage to Chelsey and ye Rancounter wth ye Watch	00=05=00
	Ol: Vitrioli 1/2 lb and Salpeter 1/2 lb ...	00=04=08
20.	Reciever	00=02=06

IN DORSO.
Auggust 10th, 1667.

Received according to the Contents within written of Mr. Morris and Mr. Clayton the sum of Twenty-five Pounds Six Shillings and Four Pence I say

£ s. d.
25 : 6 : 4

JACOB KUFFETER.

On the outside of the paper when folded:

The Duke of Bucks ordr for 25—6—4 and the Bill for the same.
Augo. 1667.

The bill of Jacob Kuffeter (? a Dutchman) points to several things in the Duke's requirements. First there are the instruments of simple chemical experiments. A charne or churn glass is, I believe, what we should now call a beaker. A cohobating glass or pelican is now called a returning or reflux still or retort. A pottle glass or bottle was one holding half a gallon. A bolts head was, and still is, a section of a sphere, mostly of glass, which was used to condense the vapours of volatile substances such as camphor or benzoin, also for evaporating solutions as was the vaporing glass.

The chemicals are of the simple kind too.

Sal tartari was the crude tartrate of potash or argol from wine casks which had been calcined to such an extent that the residue was an impure mixture of carbonate and hydrate of potash, with lime and other salts.

Rhenish tartar was the purest form of crude tartrate of potash found in the casks of hock and moselle. It was white in colour, whereas most other varieties were dark.

"*Verdigreece*" was impure acetate of copper. Often, however, the term was applied to green fatty acid salts of copper, produced on the metal when left in contact with stale fat or oil.

Antimonii. This was the purified sulphide of antimony, then sold in sugar-loaf shaped castings.

But among the simple chemicals and apparatus appear several items characteristic of the Duke. There is the "spirits of guaiacum," which in those days was a "sovran remedy to cure the wounds acquired in Venus' wars." Then on June 18th we find "Waterage [that is, boat hire] and the Rancounter with the Watch, 5 shillings." Evidently a street row, which his Grace was very fond of getting into. The prices seem reasonable enough, but as compared with present prices must be multiplied by about five times at least.

It is curious how fond many clever and learned men were of what might be called messing about with chemicals, much as schoolboys do now with a set of Statham's chemical experiments. Dr. Johnson confesses to having a small chemical laboratory, and that the making of essences was more or less an elusive pleasure, not to say a waste of time. At the time of this bill many celebrated men were doing the same; among them, if I remember rightly, was Prince Rupert. The Dutch seem to have been great workers in chemistry, both pharmacopoeial and industrial. The first official list of drugs and their prices was issued by the Apothecaries' Society in 1685, and their working chemist was a Dutchman.

The Mr. Wharton mentioned may possibly be George Wharton (1617–81), afterwards Sir George Wharton, Bart. He was greatly given to all kinds of trafficking in alchemy and astrology.

F. WILLIAM COCK.

BRITISH EMPIRE CANCER CAMPAIGN.

EXPERIMENTAL STUDY OF MALIGNANT DISEASE.

THE annual general meeting of the British Empire Cancer Campaign was held on July 8th at the House of Lords, with H.R.H. the DUKE OF YORK, the president, in the chair.

The Duke of York, in his presidential address, called attention to the work accomplished in the few years since the foundation of the Campaign, and made special reference to its great achievement in organizing the International Conference on Cancer, held in London last July. Probably the most important outcome of this conference was the national awakening to the possibilities of radium in combating cancer; the Campaign had played an active part in bringing about the scheme of the National Radium Fund, and a number of the members of the Grand Council were associated with the appeal itself. His Royal Highness expressed gratification at the establishment of the Garton prize of £500 and medal, which in 1931 would be awarded to any person or group of persons submitting the best essay on the early diagnosis of cancer, and in 1933 for an essay on some other aspect of the cancer problem. Since its inception, he continued, the disbursements of the Campaign, which had been directly applied to the assistance of cancer research, amounted to over £100,000, and to secure a continuous flow of contributions to this great object would call for strenuous effort on the part of the Appeal Committee. It had always been his experience that where a campaign was handled with business-like efficiency, as this one was, one could rely with confidence upon the wholehearted support of the generous British public.

Lord READING, having proposed a vote of thanks to the Duke of York for accepting the office as president and for his interest in the Campaign, Sir THOMAS HORDER submitted the annual report for adoption. The greatest result of the International Conference, he said, had been the impetus it had given to cancer research throughout the

world. A significant effect was that the accumulated experience in regard to the relative efficiency of radium treatment had been crystallized, and thereby in large measure a stimulus had been given to the formation in this country of a National Radium Fund. He would like, however, to mention a grave danger. In the minds of many people who, while intelligent, were yet uninitiated in medicine, there might have arisen an unfounded belief in the complete efficacy of radium as a cure for cancer; such a belief, if carried into practice in any case in which the growth was completely removable by operation, might have very unfortunate results for the patient. Perhaps in the course of time, as a result of wider experience and improvement in technique, radium might well come to equal, or even to exceed, operative measures in efficiency. At present, said Sir Thomas Horder, it was in many cases the bounden duty of the doctor acting in the patient's interest to overrule the not unnatural antipathy to surgical measures; it was none the less true that the number of cases to which radium was applicable, and in which brilliant results were achieved, increased every year. He would sound one further note of warning: it was open to doubt whether many of the institutions to-day advertising for money wherewith to purchase radium had upon their staffs men and women qualified to use it. The Radium Commission would have to satisfy itself that those into whose hands this powerful but dangerous remedy was placed had been properly trained in its use. Some of the money might even be devoted to the provision of such training.

Mr. J. BEAUMONT PEARSE, having seconded the adoption of the report, the Grand Council held its quarterly meeting, and re-elected Lord Reading as chairman and Lord Dawson of Penn and Sir John Bland-Sutton as vice-chairmen.

THE SIXTH ANNUAL REPORT.

In opening the sixth annual report the Grand Council is able to record the fact that by central co-ordination of the investigations conducted under its auspices not only has duplication been avoided, but researches considered unlikely to yield satisfactory results have been brought to a close. These are desirable economies, but the Grand Council points out that, failing increased public support, it may find it necessary to limit the amount of its grants to institutions and individuals engaged in cancer research. It feels sure that the public does not desire that there should be parsimony in subsidizing an effort of such importance, and that it is only necessary to draw attention to the need for increased financial support to stimulate further and adequate subscriptions.

Treatment by Radium.

During the past year a great deal of work has been carried out to ascertain the most effective dosage of radium in the treatment of malignant disease and the most suitable form of screening required. It is now generally recognized that the curative effect of radium is due to gamma irradiation, and, beta irradiation being undesirable, it is necessary to subdivide and distribute radium salt into containers which give the maximum screenage. Platinum, which on account of its density is the best filter available, is now generally used as the standard screen, its thickness varying with the amount of radium contained per unit of length. In practice it has been found that 0.5 mm. of platinum for 0.5 mg. of radium in a length of 1 cm. screens off 99.6 per cent. of beta rays, but to avoid the occurrence of radium necrosis in the region of radio-resistant neoplasms, which have to be treated by prolonged irradiation, it has been found necessary to increase screenage to as much as 1 mm. of platinum.

Careful investigations have been made into the best method of constructing and using the so-called radium bomb, by means of which rays from a large mass of radium, suitably screened, can be brought to bear upon the tumour from a distance outside the body. Owing largely to the radium shortage the bomb, which must contain almost a gram of radium, has hitherto been very little used in this country; but with the increased supply of radium soon to be made available by the National Radium Fund it is proposed to construct several such bombs, and to investigate how they may be adapted to obtain the best therapeutic results, combined with the greatest economy in the use of radium.

A large number of the figures from the various research centres deal with cancer of the uterus, in which cures estimated on a basis of three years' freedom from recurrence amount to about 50 per cent. Results of treatment in cancer of the rectum are less satisfactory, owing to the far greater difficulty of access to the tumour. The technique, however, has become standardized, and better results may be expected in the future.

X-Ray Therapy.

During the year research work has been continued on the use of hard x rays in the treatment of cancer. The so-called stimulation effect of small and repeated doses has been carefully studied in animals, and it is interesting to note that so far it has not been possible to verify the supposition that under-dosage stimulates rather than retards the growth. It has been shown that in certain situations x rays alone cause complete disappearance of the growth, patients having remained free from a recurrence for several years. Though the percentage of such cures has hitherto been disappointing, it seems possible that a combination of x rays with radium may give better results than the use of either of these therapeutic devices alone. The danger that x-ray workers run from slight leakage in the apparatus has served to initiate an investigation of the effect on the blood of very small and repeated doses of x rays extended over a long period. Animals have been exposed to daily doses of x rays of about the same size as those to which the radiologist might be exposed in the course of his work. It has been found that many months elapse before notable changes occur in the blood, and even then there is no distinct reduction in the number of lymphocytes, although the polymorphonuclear leucocytes increase. No evidence of impaired health can be detected in animals which have been thus treated for just over a year, but to reproduce the conditions under which the radiologist works it will be necessary to continue the exposures for very much longer. It must be remembered that the whole effect of irradiation does not manifest itself at once; there are persistent and usually progressive sequelae which must always be considered in planning treatment. It is possible, therefore, that in the animals just discussed there may still arise signs due to the long-continued treatment with x rays. On the clinical side blood examinations have been performed at frequent intervals during treatment of selected patients who have been subjected to irradiation by carefully measured doses of x rays. The correlation of the haematological changes with the physical dose of x rays has, so far, not been completed, but already the blood changes which indicate that treatment should be suspended are being recognized. In man, just as in the rabbit, it has been found that a rise in the number of the hyaline leucocytes to a level about that of the lymphocytes is a sign that the total dose administered has been too large; fortunately, it has also been found that the blood will return to normal if x-ray treatment is suspended, though several months may elapse before it can safely be resumed. As exposure to ultra-violet radiation appears to hasten the return of normal haematological conditions, it is possible that x-ray treatment, combined with exposure to ultra-violet rays, will permit of the use of a somewhat more *intensive x-ray therapy*.

The Virus of Rous Sarcoma.

Several investigations have been carried out to ascertain the nature of the virus of Rous sarcoma. It has previously been shown that the infective agent in filtrates is less easily destroyed by ultra-violet rays than are the common pathogenic bacteria. In the present experiments the time required to destroy the virus by ultra-violet rays is being compared with that required to destroy various antibodies and ferments, among them diastase, trypsin, complement, and haemolytic amboceptor. The results indicate that the susceptibility of the infective agent of the Rous sarcoma

lies between that of the ferments and of the bacteriophage, it being considerably more easily destroyed than in trypsin—the most susceptible of the ferments examined. Attempts to produce artificial tumours in fowls by the inoculation of embryo pulp and arsenic have so far failed, the results obtained last year being, therefore, unverified. Work on this subject, however, is still in progress.

Production of Immunity against Cancer.

Various methods for the prevention of cancer, or of its recurrence after operation, have been investigated, and last year the latter was shown to be possible in the transplantable tumours of rats. Jensen's rat sarcoma or rat carcinoma can be cured by injecting 1 per cent. formalin into the tumours, and, by this vaccine treatment, cured rats are rendered immune against subsequent implantation of the tumour cells concerned. The study of two spontaneous chicken tumours has yielded further evidence of the existence of antibodies having a special toxicity to cancer cells. Fragments of these tumours injected into rats produced in the serum antibodies which killed not only cultured chicken tumour cells, but cultures of mouse cancer cells as well; applied to cultures of normal mouse tissue they were quite harmless. While, however, vaccine treatment has readily brought about the disappearance of transplantable tumours, it has not been so effective in the treatment of spontaneous tumours.

Carcinogenic Agents.

It has been shown that mere prolonged irritation will not produce cancer, but that some other factor, the exact nature of which is not yet clear, is also necessary. There is no increase in the percentage of tumours obtained when the concentration of cancer-producing substances is raised above a certain critical level. Further observations in this connexion, bearing especially on the use of carbon dioxide snow as a carcinogenic agent, on the effect of tobacco smoke, and on artificially induced hyperplasia, have already been described in our issue of July 6th, at page 25.

Cancer of the Rectum and Alimentary Tract.

It is hoped that careful studies now proceeding of the mechanism by which cancer of the rectum and alimentary tract spreads from the primary tumour by way of the lymphatic tissues and blood stream will enable the surgeon more completely to eradicate the disease, either by planning more extended operations or by inserting radium along known areas of spread. In the vast majority of cases of rectal cancer there is nothing in the patient's history pointing to a previous condition which might be regarded as a forerunner of tumour. No confirmation of the views that long-existent haemorrhoids, chronic constipation, or, except very rarely, chronic pruritus ani, may give rise to cancer has been found. On the other hand, both experimental and clinical observation have shown that the onset of carcinoma is commonly preceded in different organs of the body by a pre-cancerous condition of the epithelium. According to studies made at St. Mark's Hospital, the earliest recognizable lesion in the development of cancer of the rectum is a hyperplastic change taking the form of irregular epithelial proliferations, scattered over an extensive area of the bowel. This condition is followed by the appearance of visible adenomata, numerous and often separated from each other by several inches of mucous membrane. The bowel may remain in this state for many years, or, at any stage in the epithelial proliferation or in the growth of an adenoma, the epithelium may assume the invasive properties characteristic of cancer. It would appear, then, that carcinoma formation is an accident happening to a previously existing adenoma. With the development and dissemination of the malignant tumour, the neighbouring epithelial proliferations and benign tumours tend to retrogress and disappear, so that they are less evident in association with large malignant ulcers. It is as yet early to estimate the value of investigations upon the pre-cancerous state, but it is suggested in the report that this line of research has in many cases already prevented the development of bowel cancer.

MATERNITY AND CHILD WELFARE CONFERENCE.

THE PROBLEM OF MATERNAL MORBIDITY.

DURING the week beginning July 1st the annual conference on maternity and child welfare, organized by the National Association for the Prevention of Infant Mortality, in co-operation with the Maternity and Child Welfare Group of the Society of Medical Officers of Health, was held at the Friends House, Euston Road. Mr. ARTHUR GREENWOOD, M.P., Minister of Health, addressed one session of the conference, over which Mr. E. B. TURNER presided. Mr. Greenwood emphasized the value of antenatal care in reducing maternal mortality, and said that he hoped it might be his privilege before he laid down his office to do something to strengthen the health services relating to maternity and infant welfare, to improve the status and opportunities of the midwife, and to ensure that, as far as was humanly possible, the terrors of confinement were removed from the mother.

Maternity Nursing.

A whole day was devoted to the subject of maternal morbidity, approached from the standpoint of maternity nursing, on which subject a paper was read by Dame JANET CAMPBELL. There was general agreement, she said, that maternity nursing as a rule was not so adequate or satisfactory as it should be, and that an improvement in this service could scarcely fail to lead to some reduction in morbidity, perhaps also in mortality. To secure the necessary improvement untrained women must be prevented from practising at all as maternity nurses, while encouraged to act as home helps, and recognized maternity nursing must be limited to women who were qualified midwives, who should be given a more adequate training in nursing, and have it made practicable for them to devote sufficient time and attention to all their patients. Dr. J. S. FAIRBAIRN spoke of the variable quality of the type of women serving as maternity nurses; they ranged from the handywoman or self-styled nurse to the certificated midwife. Unfortunately, the large class of people who were barely able to afford the services of a doctor were apt to engage a nurse without training because of her cheapness, and perhaps because she would do menial service in the house. Until every woman had a trained midwife to nurse her, and the handywoman and the "nurse" of inferior training were wiped out, puerperal morbidity would remain more rife than it should be. The experienced midwife regarded it as her primary duty to secure normal labour and lying-in. Miss E. DOUBLEDAY, representing the College of Nursing, thought that the public needed to be awakened to the fact that facilities for maternity nursing existed, both for those who could pay for the service and for those who could not.

At the same session Mrs. CHALMERS WATSON, M.D., spoke of the value of milk irradiated with ultra-violet rays as a curative agent for rickets. Her own clinical investigations at the Royal Infirmary, Edinburgh, bore out the indications from German researches that this was a therapeutic factor of importance.

Causes and Extent of Maternal Morbidity.

Mr. COMYNS BERKELEY dealt with the subject of maternal morbidity with special reference to abortions. He thought the importance of abortion as a cause of morbidity could not be exaggerated, more especially as there was reason to believe that criminal abortion was on the increase in this country, as it certainly was in other European States. It was with criminal abortions—those self-induced being included in this category—that most of the trouble with regard to subsequent morbidity arose. The absence of expert knowledge of the genital anatomy, and of any attempt to ensure antisepsis and asepsis, also the necessity of preserving secrecy, led to a large number of deaths, much misery, and perhaps lifelong invalidism. In natural or legitimate abortion sepsis and injury were of far less

frequent occurrence. The injury associated with abortion was generally perforation of the uterus, the result, in nearly every case, of criminal interference. After turning to other conditions productive of maternal morbidity, but in which the fact of abortion did not enter, Dr. Berkeley said that a vast amount of morbidity was due to ignorance, carelessness, and undue haste. The key to the situation was education—education of the practitioner, the student, the midwife, the pregnant woman herself, and the community generally. There should be some agency whereby every pregnant woman would have the importance of ante-natal supervision (and, if necessary, treatment) brought directly to her notice. A large amount of work had to be done before the community could be made fully to realize the vital importance of ante-natal care and efficient care during labour. The lay public must be made to understand that labour was in a sense an operation, and required just as much forethought. People would pay an adequate fee, more or less willingly, for a surgical operation or a specialist opinion, but would jib at paying an utterly inadequate and even absurd fee for the confinement of their wives. With regard to the difficult question of abortion, he supposed it was Utopian, but much misery and much maternal morbidity could be saved if abortion were made compulsorily notifiable.

After Miss MUSSON, secretary of the National Council for the Unmarried Mother and her Child, had spoken on the devious ways in which abortifacient drugs were brought before the public, Dr. DOROTHY MENDENHALL described the position in regard to maternal mortality in the United States. The deaths of women from puerperal causes in the registration area in the United States in 1921 were 68 per 10,000 live births, and in 1927 the number had declined to 65; but as in the meantime certain States which already had a high maternal death rate had come into the registration area, the improvement was rather better than the figures suggested. A preliminary tabulation of the causes of death in seven States in 1927 showed that puerperal septicaemia accounted for 40 per cent. of puerperal deaths, and that abortions preceded 42 per cent. of the deaths from septicaemia.

Dr. F. H. SCRASE (medical officer of health, Hampstead) urged the formation of panels of consultant gynaecologists and obstetricians in order that skilled assistance might be readily and freely accessible to the general practitioner in time of difficulty. Investigations in Hampstead showed that about one-half of the stillbirths were attributable to conditions where skilled assistance would have been of material help, and might have obviated the stillbirth. Consulting obstetricians, who could only be called in by a medical practitioner, and whose fees were guaranteed by the local authority, had now been appointed in several districts, and up to the present none of the difficulties anticipated in some quarters had occurred.

The Problem of Abortion.

During the conference a special medical session was organized by the Maternity and Child Welfare Group of the Society of Medical Officers of Health, when Dame LOUISE MCILROY spoke on the problem of abortion. She said that there had been an enormous increase in the number of abortions since the war. Formerly it was chiefly unmarried women who were concerned, but her experience in hospital was that now the majority of the victims were married women. Behind the trouble, to a large extent, lay unemployment and housing difficulties. Dealing first with spontaneous abortion, she said that this was being reduced with efficient ante-natal treatment. As for therapeutic abortion, this was undoubtedly lawful, but was it legal? She could not find any explicit reference in any statute to establish its legality. It was undoubtedly a confession of failure, and with further knowledge she believed that abortion as a method of treatment would cease. Was it an over-conscientious view on her part to regard the ovum as a life from the beginning, and that life should not be interfered with except for very grave medical reasons? The question arose acutely in pregnancy resulting from rape. French medical opinion during the war, when some French women had been violated by German soldiery, was that the pregnancy should go on unless there was a medical reason for interference. She supposed that was the correct view, though one's sympathies were with the victim. In the case of criminal (including self-induced) abortions, uterine injections appeared now to be the favoured method. Women of good (even university) education would take drugs to induce abortion, while stopping short of operation. As remedies one could only suggest the inculcation of a higher moral outlook. The grave danger attendant and consequent upon abortions might be impressed upon women. She also desired to see notification of abortion, under a confidential system, and the suppression of advertisements of abortifacients.

Professor BECKWITH WHITEHOUSE said that the frequency of abortion to-day on the Continent was appalling. It was stated that in Hamburg in 1926 there were two abortions for every three births. In this country he could not think that the figures approached to anywhere near those of Germany. Recently he analysed the incidence of abortion in 1,000 patients admitted successively to his ward at Birmingham General Hospital from 1924 to 1928. These women had produced 3,228 children, and in addition had had 597 abortions. He made a similar investigation for three pre-war years, 1911–13, when 616 women were responsible for 2,594 pregnancies at term and 524 abortions. The greatest number of abortions occurred in the most fertile women; this was specially marked in pre-war cases, when families were larger than now. He was rather inclined to think that many of these abortions were the result of impaired reproductive capacity, and due to defective vitality in the germ plasm. The extreme complexity of ante-natal physiology was gradually being revealed. It was known that if certain vitamins were withheld from the diet of pregnant rats the animals always aborted and the embryos were defective in development; also that if trauma were applied to the corpus luteum at any time until the placental circulation was established the decidua broke down and the developing ovum was aborted. It was conceivable that many cases of abortion that followed sudden mental and physical shock were caused by inhibition of the corpus luteum. Another important line of investigation in the causation of abortion was the physiological function of the endometrium. He believed that during the first weeks of gestation and before placental circulation was established, the secretion of the uterine glands was an important factor in the nutrition of the embryo. Why should the calcium and iodine content of the secretion of the uterine glands be so high if not for the welfare of the developing ovum? He knew of several instances of women, who habitually aborted, successfully going to term when treated with heavy doses of calcium and iodine and a diet rich in vitamin E. One patient who had had six abortions and had reached the age of 40 produced a child weighing over 10 lb., for which he had to perform Caesarean section. He believed that too important a role was attributed to syphilis as a cause of repeated miscarriage.

Dr. F. J. MCCANN considered that many abortions occurred because women did not get sufficient nutriment to keep the reproductive power going. He made a plea for special abortion wards. Mr. E. B. TURNER said that fifty years ago the abortionmonger carried on in a hole-and-corner way, but now the practice appeared to be countenanced by many people in good position and reputation, by whom it was not regarded as a criminal act. He thought it ought to be proclaimed from the housetops that an attitude of compliance with a patient's importunity on the part of a member of the profession was wrong. He also made some straightforward remarks on the need for maintaining strict professional secrecy.

The rest of the discussion was rather side-tracked by some speakers who put forward birth control as a necessary and innocent alternative to the practice of abortion; but one practical outcome of the debate was, at Dame Louise McIlroy's suggestion, the appointment of a small committee to seek the co-operation of the Medico-Legal Society in an investigation into the prevalence of criminal abortion and the death rate therefrom.

British Medical Journal.

SATURDAY, JULY 13TH, 1929.

DIATHESES AND TEMPERAMENTS IN A NEW LIGHT.

A PROFESSOR of clinical medicine who inscribes on the wall of his classroom in Genoa the aphorism "Anatomy and physiology separate the organs; the clinic reunites them," may well be expected to provide for his pupils some inspiring and interesting lessons. This expectation is amply confirmed when from the classroom we pass to the printed page, and read Professor Nicola Pende's *Constitutional Inadequacies*.[1] A modest volume of some 250 pages, it presents a closely reasoned argument based upon multiplied observations and a considerable scientific equipment; and the reading of its English translation is an enjoyable experience which we owe to the linguistic and literary abilities of Dr. Sante Naccarati.

The principal thesis which Dr. Pende advances is that the individual clinical problem can be fully understood only by the study of the patient's personality. This proposition—let it be admitted—does not on the face of it present a particularly novel or original quality. That the physician ought to treat the patient and not the disease, and that personal idiosynerasies display themselves in medicine as in other fields, are phrases familiar in many exhortations, though neither the one nor the other pretends to much in the shape of scientific explanation or practical guidance. Further, developments in medicine during the last generation or so have rather obscured the personal quality of the patient as an important element in the clinical discussion in which he believes himself to be the central figure. Preventive medicine cultivates a communal rather than a personal outlook, and under the influence of bacteriology and other etiological studies the individual patient has largely appeared as a victim on whom agents from without work their wicked will, while he himself is catalogued as merely one in a group of more or less numerous units suffering from discomfiture by some invading force. The application of general doctrines to individual sufferers, rather than the identification of particular personal qualities, has been the main ambition of clinical medicine. Under such influences terms which were at one time common in the medical vocabulary have to a large extent disappeared. *Temperament, diathesis, constitution*, have their pages and chapters throughout the centuries, but little has been heard of them for something like a generation, though now and again one listens to an expressed preference for a medical adviser who has had the opportunity of studying the family "constitution"—a plea perhaps condescendingly accepted with the tolerance due to a popular and harmless superstition.

Now, according to Dr. Pende's claim, the wheel has come full circle, and clinical medicine, alike in its etiological and therapeutic aspects, must include the study of "the constitutional personality" of the sick man; hints to be found in Hippocrates and in the humoral pathology must be recognized as of high value; and temperaments and diatheses are to be accepted as capable of confident identification and of groupings and classifications for which, to those who have eyes to see, appropriate pigeon-holes are duly waiting. There is, however, a difference between the old and the new. Whereas formerly the classification of temperaments depended largely on general impressions, the new classification professes a basis of measurements, or at least of morphological, psychological, or other recognizable and definable facts. If some of the names are old friends it is not so much their tradition and ancestry that they boast, though they do not disown these; rather their claim to attention is the shining light of scientific accuracy which they display upon their foreheads. In short, the argument is that there can be recognized by the physician "types" of constitution; that while in each group there are extreme and conspicuous members, the group includes also degrees and gradations which are not less significant because they are less obtrusive; that important agencies in the causation of the structural and functional inadequacies or maladjustments which explain the constitutional peculiarities of the individual are heredity and endocrine disturbances; and that the recognition and accurate interpretation of these peculiarities in each patient is a necessity for a well-judged diagnostic and therapeutic practice.

The earlier part of the book is occupied by a discussion of the criteria which must be applied in order to determine to which constitutional group the individual belongs, while the later chapters consider in series the various anatomical and physiological systems of the body and the constitutional inadequacies to which these are subject. The study is presented as "human biotypology" or the "science of the individual" as this is related to disease, whether determined, on the one hand, by structural inadequacies or physiological discords arising within the body itself, or, on the other, by the action of external agents and the particular quality of the patient's response, modified, as this may be, by the constitutional characters of individual tissues. The purpose of the argument may be summarized as an attempt to revive in clinical medicine and in clinical psychology the study of the factors which both give individuality to the patient and influence the degree or character of his reactions and responses.

In his preface Dr. Pende pays a cordial tribute to other teachers, and especially to De Giovanni, who, he writes, "for many years attacked the communistic regime which prevailed in medicine and under which the individual characteristics of the patient were ignored." The book altogether is a most interesting and engaging one, and even if, as we may fairly say, English medicine has always placed a sufficient emphasis on the personality of the patient, Dr. Pende has provided both a justification for this attitude and a plea for its cultivation and extension upon the basis of exact observation and scientific grouping. His pages are not for the passing moment; on the contrary, they call for careful study, and this they most certainly deserve.

[1] *Constitutional Inadequacies*. By Nicola Pende, M.D. Translated by Sante Naccarati, M.D., D.Sc., Ph.D. With a foreword by George Draper, M.D. Philadelphia: Lea and Febiger. 1929. 3.50 dollars.

POLIOMYELITIS IN MANITOBA.

IN the late summer and autumn of 1928 an epidemic of acute anterior poliomyelitis occurred in the province of Manitoba, 435 cases in all being reported. These cases afforded an opportunity for a close study of some of the problems of this disorder which still require solution, and in 161 instances the use of convalescent serum and a careful clinical study of the results brought to light many points of interest. The work has been done by the Medical Research Committee of the University of Manitoba, and is published at the request of the Ministry of Health and Public Welfare by the Great-West Life Assurance Company.[1]

A paper on the distribution of cases illustrates some of the difficulties concerned with the spread of the disease. The epidemic reached its peak in September, and nearly one-third of the patients were below the age of 5 and two-thirds below the age of 10. Evidence is brought forward to show that where contact is known to have existed through more than one case occurring in the same family, or revealed by some other information, such cases were usually related by time intervals of less than two days or of six or seven days. The latter period appeared in a larger number of pairs of cases in the same family than did the short interval. It is concluded that "it is reasonable to consider as a distinct possibility transmission of the disease from individual to individual *in some way* at present not definitely known." Another important series of papers deals with the preparation and use of convalescent serum for the cases of poliomyelitis. This serum was obtained from individuals who had previously suffered from the disease. Through the health authorities in the city of Winnipeg a fairly complete list of previous cases of poliomyelitis which had occurred in the city was prepared, and, although only a few individuals could be quickly traced, sufficient serum was obtained to meet the early demands. Donors were paid at the rate of 5 dollars for 50 c.cm. of blood or less, and 10 dollars for more than 50 and less than 100 c.cm. As soon as the demand for serum began a serious shortage of donors was apparent, and various measures were tried, such as obtaining serum from neighbouring towns and even from Paris. In September the newspapers were asked to help, and, thanks to the publicity thus afforded, a large number of donors were obtained. The serum used was Wassermann-negative sterile blood serum, pooled from six to eight donors. Of the cases seen by the consultants specially appointed to investigate the epidemic, 161 were selected on a basis of positive diagnosis and accurate records. The serum was given by the intramuscular route, standard doses of 25 c.cm. being employed in the pre-paralytic stage of the disease. Over 8,000 c.cm. of serum were administered during the course of the epidemic. Of the 161 cases used for analysing the results 74 received serum in the pre-paralytic stage of the disease, 54 received no serum, and 33 cases received serum too late to be of much value—that is, after the onset of paralysis. Within a few hours following the use of serum the usual result was a drop in temperature and complete recovery from most of the symptoms.

Dealing with the eventual results, the report shows that among the 74 cases receiving serum in the pre-paralytic stage no deaths occurred, and only 5 cases showed any residual paralysis—that is, approximately between 6 and 7 per cent. Among 33 cases given serum after the onset of paralysis there occurred 11 deaths and 15 cases of residual paralysis (or 45 per cent.), while among the 54 cases receiving no serum there were 6 deaths and 34 cases of residual paralysis (or 64 per cent.). It is recognized that the virus of the disease becomes attenuated in the later stages of an epidemic, and also that the serum-treated cases were in general milder cases, while the controls were for the most part those seen after paralysis had occurred; but despite these objections, which are well met in the report, there seems not the slightest doubt of the value of convalescent serum administered in the pre-paralytic stage of the disease by the intramuscular route, which is simple and safe. The pathology of the epidemic and the symptomatology and laboratory findings are well summarized in other papers included in this very excellent report, which should be carefully studied by all interested in the control and treatment of this essentially crippling disorder.

THE CAMPAIGN AGAINST VENEREAL DISEASE.

THE fourth imperial congress organized by the British Social Hygiene Council has been held in London during the past week. Representatives of eight Dominion Governments (State and Provincial) and twelve Colonial Governments, as well as of universities and voluntary organizations, were present. The general subject debated by the congress was the international situation with regard to venereal diseases, and reports on the progress of the anti-venereal campaign were made by delegates from many different parts of the Empire. Two sessions were devoted to educational propaganda, in particular to the question how a biological outlook on life and its problems could be developed by those in charge of university, public school, and elementary education. The delegates dined together at the Hotel Cecil on July 8th, when the company included Lord Passfield, Secretary of State for the Dominions and Colonies, Dr. Drummond Shiels, M.P., Under Secretary of State for India, and representatives of the League of Nations, the Ministry of Health, the Scottish Board of Health, and colonial health administrations. Lord Passfield (who will always be better known as Mr. Sidney Webb) said that he was glad that one of his earliest social functions as Secretary of State should be connected with the furthering of the moral and social welfare of the various races making up the British Empire. He paid a tribute to the patient and persistent work of the British Social Hygiene Council during the past decade. The council had carried out work under the aegis of the Colonial Office since 1920, when, on a grant of £7,500 provided by the Treasury at the request of the Colonial Office, three commissions were dispatched, each consisting of a medical and an educational specialist, to the West Indies, the Mediterranean, and the Far East. These commissions might be said to have initiated the recent move throughout the Colonial Empire in handling this difficult problem of venereal disease. Out of the liaison between the council and the Colonial Medical Service had grown the Imperial Social Hygiene Congresses, which had become biennial events of great utility. The council was called upon to deal with one of the worst scourges of mankind, which only in recent years had received the serious attention it deserved. "Will you forgive me if I add a few words, inappropriate perhaps to an after-dinner occasion," the Secretary of State went on, "on the philosophy that I detect in the work that you are doing, in so many different countries, with such varied devices and expedients, legislative and administrative, and with so great a promise of success? Forty-eight years ago, when I entered the Colonial Office—in a different grade from

that which I hold to-day—the only action taken by the community with regard to venereal diseases was in the nature of repression. Society rang the changes on punishment, obloquy, blame, ostracism. We even regarded the ill health, disease, and suffering of the victims—some of them innocent victims—as instruments in the social punishment we presumptuously meted out. Registration, regulation, hospital treatment—whatever was done—were all parts of a framework of repression. I must not tire you by even a passing tribute to the noble men and women who began to teach a more excellent way. The policy that the British Social Hygiene Council has been working out with ever-increasing approval may be described as the substitution for a social framework of repression of a social framework of prevention. To construct such a framework is a difficult task. It is easy to punish, but how futile! We can be prompt to blame, but in our ignorance how unjust! It is plausible to regulate what we do not know how to prevent, but how unsuccessful! To grow the new social tissue involved in better education in biology and physiology, in more healthful conditions of leisure and recreation, in medical treatment both up to date and adequately equipped and universally accessible, together with the strong arm of the law vigilant to protect the child, the woman, and also the man against abuse—all this calls for an enormous amount of personal service of philanthropic people, it requires from all Governments concerned not only cordial co-operation, but also money, and, hardest of all, it demands from statesmen and officials what someone has called the intolerable toil of thought."

IODINE AND GOITRE.

A RECENT study by Dr. Eric Adlercreutz of Helsingfors of the distribution of goitre in Finland and its relation to the iodine content of water[1] is valuable in affording a corrective to any narrow view of the causes of this condition. In his investigation Adlercreutz used two methods: by carefully checking the replies to a questionary sent out to all practising doctors in Finland he obtained what appears to be a just view of the distribution of goitre throughout the country; and by analysis of water samples from a large number of localities he obtained the data by which correlation could be effected between the incidence of goitre and the distribution of iodine. His work, however, is based on the unproven assumption that the iodine content of water is a fair reflection of the iodine in the soil, air, and food produce of its neighbourhood, and it takes no account of the fact that, except among primitive peoples who live off the land they cultivate, iodine intake is only slightly connected with the iodine content of the environment. His main conclusion is that in Finland there is generally a positive correlation between the prevalence of goitre and a low iodine content of water, but that there are many exceptions, notably at Vetil, where water of low iodine content supplies both a definite goitre area and its non-goitrous surroundings, and in Värtsila, where goitre is associated with water of high iodine content. From the exceptions he deduces that deficient iodine is not the only cause of goitre, and he recognizes, moreover, that even a demonstration of a strict correlation between goitre and the iodine content of the environment does not completely prove that between these facts there is a causal relation. One of the greatest difficulties in an investigation of this kind is in the accurate quantitative analysis of samples of water containing minute quantities of iodine. Adlercreutz, after six months' practice, adopted von Fellenberg's method, and appears to have taken great care to ensure the reliability of his findings, conducting a number of duplicate analyses with consistent results. But what he failed to do, and what in such a difficult estimation would appear to be essential, was to carry out regularly double analyses, one of the sample itself, the other after a known quantity of iodine had been added. Even if it is granted that the published estimations are to be relied upon to within 100 per cent.—with von Fellenberg's method a reasonable margin of error—there appear to be, as Adlercreutz himself has shown, large variations among samples of water from the same source taken at different times. A spring water, for example, tested in this way showed variations of iodine content from 0.07 to 0.30 part per thousand million. A single analysis of a water may give, therefore, not only an erroneous idea of the general iodine richness or poverty of the surrounding district, but of the average iodine content of the water itself. Adlercreutz analysed altogether 74 samples of water from 60 places in Finland, and eight samples of purified town supplies. The iodine content of spring waters, though not of the waters of rivers, lakes, and town supplies, appeared to be related with the prevalence of goitre, and, arbitrarily choosing the figure of 40 parts per hundred thousand millions as his criterion, above and below which he classes water as rich or poor in iodine, he found that of 36 places in the goitrous part of the country, spring water is poor in iodine in 31, while of 24 places in the non-goitrous part it is poor only in 8. If, however, the average iodine content of these waters in the goitrous and non-goitrous areas is compared, the differences, on account of the large variations, are statistically not very significant. The figures, indeed, are necessarily so uncertain both for the iodine content of water and for the prevalence of goitre that it seems doubtful if Adlercreutz has succeeded in establishing a conclusive association between them. His final conclusion is that "McCarrison's view of the multiple causes of goitre seems the most feasible. These causes are apparently different in different places (perhaps also of different intensities), a fact which may probably be connected with the prevalence of more than one type of endemic goitre."

CONGRESS OF BRITISH AND AMERICAN ORTHOPAEDISTS.

THE British and American Orthopaedic Associations held a joint meeting in London, at the House of the Royal Society of Medicine, from July 4th to 6th. The various sessions were presided over in turn by Professor E. Hey Groves and Dr. Fred Albee, presidents respectively of the two organizations, and were attended by about 150 members, of whom 60 had crossed the Atlantic. In addition to a full programme of lectures, discussions, and demonstrations, the members attended an evening reception at the Royal College of Surgeons, where they were received by Lord Moynihan; they also spent half a day at Alton, where Sir Henry Gauvain gave an address on the principles of treatment employed there. Occasion was taken during the meeting to present the Robert Jones medal to Mr. E. P. Brockman of St. Thomas's Hospital—an award already announced in these columns. One debate in which some little divergence was revealed as between the British and the American view arose on a paper by Dr. H. Winnett Orr of Lincoln, Nebraska, who pointed out what he considered to be the defects in modern antiseptic methods as applied especially to infections of bones and joints. Dr. Orr, who was with the American Expeditionary Force in France, paid a generous tribute to British surgeons for what he had learnt during that experience. He put forward a method of treating compound fractures whereby the injured parts are first placed in the correct position and then the wound is packed thoroughly with an aseptic non-absorbent vaseline mass; a splint or cast is applied over a sterile dressing to keep the parts in correct position.

The original dressing is allowed to remain until healing is well established and primary consolidation of the fracture has occurred. Dr. Orr claimed that this method, revolutionary as it might seem, rested on the fundamental principles of adequate operation, adequate drainage, and adequate rest. Several of Dr. Orr's compatriots praised his method, and said that in their hands it had given extraordinarily good results. Mr. Harry Platt of Manchester said that with the general principles which Dr. Orr had laid down everyone would be in agreement, but his technical methods of putting them into operation might provoke differences of opinion. Mr. Platt felt convinced that in wound infection the usual methods of irrigation were not lightly to be set aside. It was true that complete immobilization was a necessary condition, but this was possible with the Thomas splint; he believed, however, that many British surgeons would give a serious trial to this new American practice. The familiar subject of disabilities resulting from low back derangement was brought forward in a paper by Dr. Elliott G. Brackett of Boston (Massachusetts), who urged the necessity of keeping in mind the fact that in the lumbar-sacral region one was dealing, not with the problem of an individual joint, but with a group of joints anatomically and functionally interrelated, sharing the same stress, and frequently yielding, not as individuals, but as a group. Dr. J. T. Rugh added, as an observation from his own experience, that a structural defect in size of the sacro-iliac joint in relation to the pelvis was a very frequent explanation of the cases of low backache which found their way to the orthopaedic surgeon. Dr. Arthur Steindler still believed that low back sprain would be found to fit in with the postulates of sprains in general. It had been treated as something quite exceptional, rather like a spoilt child, but when the condition came to be fully analysed its characteristics would be found to be the same as those attaching to sprains anywhere in the body. Several of the American visitors joined in the discussion on this subject, and it was pointed out that although the anatomical variation or derangement must have existed from birth, or at least ever since the individual had grown up, the low back sprain was most common in middle life. However tempting it might be to make a diagnosis of back strain simply because an anatomical variation or disarrangement had been discovered, the possibility of some pathological change in the joint, not a purely mechanical thing, should be remembered. In the discussion on reconstructive surgery in paralytic deformities of the leg, Dr. Melville Henderson expressed a strong opinion in favour of tendon transplantation, supplemented by stabilization of the smaller joints of the foot. He gave American figures to show how popular the combination of tendon transplantation and arthrodesis had become, and claimed for this operation 97 per cent. of good results, as against much lower percentages for other procedures—50 per cent., for example, for osteotomy and tendon transference. Dr. Henderson was followed by Mr. Laming Evans, who gave an exhaustive review of the work on this subject since the war, and instanced the usefulness of astragalectomy with Whitman's backward displacement of the foot. Another discussion, reinforced by clinical demonstrations and specimens, was on the treatment of fractures of the neck of the femur, with special reference to end-results. The discussion had the advantage of contributions from Professor Hey Groves, Sir Robert Jones, and Dr. Royal Whitman, who is the American protagonist for the so-called abduction method in the treatment of these fractures. Other subjects considered during the four busy sessions were the compensation treatment of scoliosis; the end-results in operation for drop-foot; and the present status of arthroplasty. Seldom can a conference have done so much in so short a time, and nine o'clock in the morning proved to be not too early an hour for the commencement of the discussions. Mr. A. S. B. Bankart, honorary secretary of the British Orthopaedic Association, on whom fell the chief burden of organizing the event, received many congratulations. The suggestion that a return visit should be paid to the United States was cordially welcomed.

INDIAN MOTHERHOOD.

In 1927 the Far Eastern Association of Tropical Medicine held its seventh congress. The delegates met in India, and the first volume (of three) reporting their discussions runs to over 800 pages.[1] It would be futile to attempt to review a volume which contains eighty-seven original papers, and reports at some length the discussions to which these gave rise. For the bulk of the book it must suffice to say that it covers general medicine and dermatology, surgery, ophthalmology, gynaecology and diseases of pregnancy, mental hygiene and psychiatry, radiology, dentistry, State medicine, general and special hygiene, maternity, and child welfare. Among a wealth of interesting material attention may be drawn to certain papers on subjects connected with Indian motherhood. Dr. Margaret Balfour, to whom the women of India owe a debt of gratitude for her devotion to their interests, contributed to the proceedings of the congress an account of the common anaemia of pregnancy. Among 11,343 labour cases in hospitals there were 244 deaths, distributed by causes as follows:

		Per cent.
Anaemia of pregnancy	87	35.6
Puerperal sepsis	43	17.6
Eclampsia	25	10.2
Osteomalacia (its consequences) ...	22	9.0
Haemorrhage	29	11.9
Other complications of pregnancy and labour	38	15.6

The anaemia resembles pernicious anaemia in a general way, but is distinguished by sudden onset, rapid course, and absence of remissions. The blood picture resembles that of the rare anaemia of pregnancy reported from other countries. McSwiney (*Ind. Med. Gaz.*, 1927, vol. 62, 487) reported its occurrence in 1.7 per cent. of 2,544 Indian pregnancies. The observed facts indicate that the condition is a toxaemia. (1) Recovery does not take place before delivery. (2) If it takes place after delivery it is complete. (3) Generally it does not occur in subsequent pregnancies. (4) It occurs in excess in primiparae. It is associated with vomiting, albuminuria, and oedema. (5) The baby is never anaemic, but is often wasted as in eclampsia. Liver treatment has caused immediate and rapid improvement. Emanuelov and Mehta report their studies of the bacteria of excreta in these cases of anaemia, with particular reference to *Clostridium welchii*. Their results appear to be inclusive so far as any determination of etiology goes, but they did find that the toxins of *Cl. welchii* isolated from human cases caused anaemia in pregnant guinea-pigs, and stillbirths and neo-natal deaths of their young. Neither malaria nor hookworm disease seems to underlie this condition. Osteomalacia remains something of a mystery. Believed to be caused by insufficiency of vitamin D, arising from deficient diet or lack of sunlight, there are anomalies of its distribution difficult to explain. "Why," Dr. Balfour asks, "should Bombay suffer and Madras escape?" Interesting figures are given to show that in Bombay not osteomalacia alone, but also anaemia and eclampsia, are very much more common among Mohammedan women than among their Hindu sisters, while native Christian women escape with very little osteomalacia indeed. In general the diet of the Christian women is the most satisfactory, then that of Mohammedans, and that of Hindus the poorest, but no particulars are given of these diets in respect of vitamin D. The outstanding difference between the three classes of women which seems

[1] *Transactions of the Seventh Congress of the Far Eastern Association of Tropical Medicine.* Held in India, December, 1927. Vol. i. Edited by Lieut.-Colonel J. Cunningham, C.I.E., B.A., M.D., I.M.S. Calcutta: Thacker's Press Directories Ltd.

to go hand-in-hand with the incidence of the diseases mentioned is the deprivation of sunlight and exercise, which affects Mohammedans most because of their observation of purdah, and the Christian women least because of the much more active lives which their religion permits them to lead. In a very interesting discussion on the organization of child welfare work in India several speakers insisted on the need of general education. Rai Bahadur Dr. Chuni Lal Bose recalled that the rate of illiteracy among Indian women was 98 per 100. It is worth noting that the most important factor in preserving infant life in early days has been shown to be sufficient and proper care by the mother, and that the improvement in infant mortality figures shown by Western lands is attributable to the steadily increasing education of the mothers rather than directly to the multiplication of infant clinics and the like. There was reason behind the opinion that in Britain the most important public health legislative measure was the Education Act of 1870.

THE SUPPLY OF ANATOMICAL "SUBJECTS" IN PHILADELPHIA.

Our old friend, the beloved Father of American Surgery, Professor W. W. Keen, having read our "Nova et Vetera" article on the supply of anatomical "subjects," in London,[1] has very kindly sent us a copy of the Anatomical Act of the State of Pennsylvania. He tells us that since the passing of this Act in 1883 "no longer are graves violated, and the supply is ample both for dissection and for operative surgery." Under this Act, which Professor Keen says is the best Act of this kind known to him, an anatomical board is constituted as follows: "The professors of anatomy, the professors of surgery, the demonstrators of anatomy, and the demonstrators of surgery, of the medical and dental schools of this Commonwealth, which are now or may hereafter become incorporated, together with one representative from each of the unincorporated schools of anatomy or practical surgery, within this Commonwealth, in which there are, or, from time to time, at the time of the appointment of such representatives, shall be, not less than five scholars, shall be and hereby are constituted a board for the distribution and delivery of dead human bodies." The Act goes on to prescribe the duties of the board and the way in which they shall be carried out. The most important section is No. 8229, under which "All public officers, agents, and servants, and all officers, agents and servants of any and every county, city, township, borough, district, and other municipality, and of any and every almshouse, prison, morgue, hospital, or other municipality or other public institution, and all other persons having charge or control over dead human bodies required to be buried at the public expense, are hereby required to immediately notify the said board of distribution . . . and shall, without fee or reward, deliver such body or bodies, and permit and suffer the said board and its agents and the physicians and surgeons from time to time designated by them . . . to take and remove all such bodies to be used within the State for the advancement of medical science." The only exceptions allowed among unclaimed bodies are those of honourably discharged soldiers, sailors, or marines of the United States or of the militia of the State of Pennsylvania. It will thus be seen that those in charge of dead bodies are given no option as to whether they will hand over the cadavers or not. Such an option, as Professor Baillie Johnston and the writer of our article pointed out, is a fatal weakness in the British Anatomy Act, a weakness which is hardly likely to be remedied in these days, when ignorant prejudice and sentimentality have more influence in high places than reason and common sense.

[1] *British Medical Journal*, May 25th, 1929, p. 968.

DEATHS BY GAS POISONING.

THE President of the Board of Trade has appointed a committee to consider the increase during recent years in the number of deaths ascribed to poisoning by coal gas supplied for domestic purposes, and to make recommendations as to any measures relating to the production and use of gas for domestic purposes which might be taken with a view to diminishing the number of such deaths. The committee consists of: The Right Hon. Sir Evelyn Cecil, G.B.E. (chairman); Sir John Robertson, M.D., professor of public health at Birmingham University; Professor R. V. Wheeler, D.Sc., director of the Safety in the Mines Research Board experimental stations; and Mr. F. J. Wrottesley, K.C.; with Mr. H. L. Spencer of the Board of Trade, Great George Street, Westminster, as secretary.

THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the *Journal* and to the *Supplement and Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

ON the recommendation of the Minister of Health, the King has been pleased to appoint Dr. Bedford Pierce to be a temporary Commissioner of the Board of Control.

THE Advisory Committee on Cancer, appointed by the Government of Victoria to advise on the leading developments abroad in the treatment of cancer, and on the steps to be taken both to co-ordinate research work in relation to the cause and treatment of cancer in the State of Victoria with similar work in other parts of the Commonwealth, and to make the treatment of cancer within the State as effective as possible, has recently issued its report to the Minister of Public Health (Melbourne: R. J. Green, Government Printer). In an interesting document the committee has summarized the more important developments abroad in research on cancer and improvement in its treatment, described past researches, and researches in progress and in contemplation in Victoria, and, having analysed the facilities for research and treatment at present available, outlined a scheme for the furtherance of research, treatment, and propaganda within the State.

THE KING.

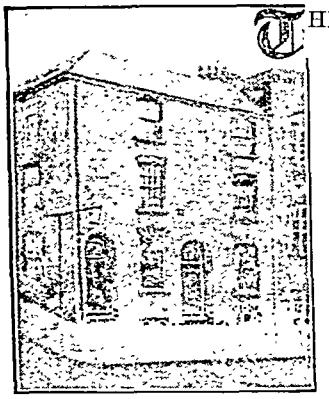
THE President of the British Medical Association, Sir Ewen Maclean, attended the Thanksgiving Service in Westminster Abbey on Sunday, July 7th, in response to an official invitation to represent the Association, of which the King is Patron. The medical men and nurses who have been in attendance on His Majesty during his illness were also present. A bulletin issued from Buckingham Palace on July 8th stated that the King was not fatigued by the ceremony of the Thanksgiving Service, but that, though his general health is good, the condition of the sinus in the right chest has not made satisfactory progress. His Majesty's visit to Sandringham has been postponed in order to allow time for further x-ray examination and consultation.

NINETY-SEVENTH ANNUAL MEETING

of the

British Medical Association,

MANCHESTER, 1929.



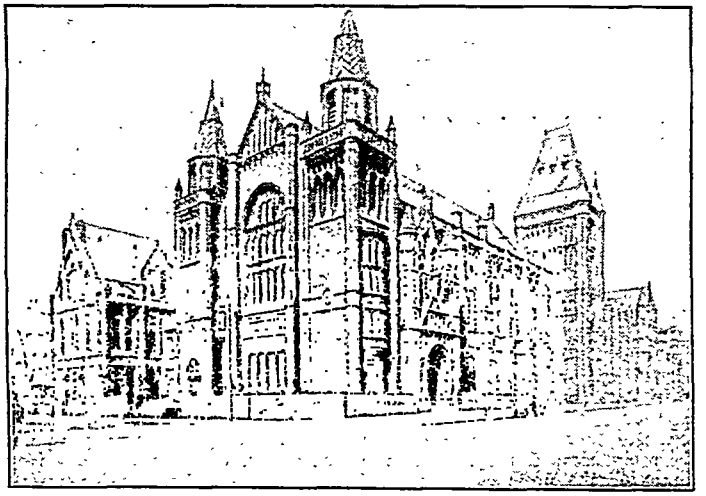
THE PUBLIC INFIRMARY IN MANCHESTER, 1752.

THE ninety-seventh Annual Meeting of the British Medical Association will be held in Manchester this month under the presidency of Mr. Arthur H. Burgess, F.R.C.S., Professor of Clinical Surgery in the University of Manchester, who will deliver his address to the Association, on "The Debt of Surgery to the Ancillary Sciences," on the evening of Tuesday, July 23rd. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations or visits of inspection. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 19th, at 9.30 a.m. The provisional programme for the nineteen Scientific Sections was published in the *Supplement* to our last issue. On the last day of the Annual Meeting (Saturday, July 27th) there will be an excursion to Colwyn Bay. We publish below the fifth of a series of descriptive and historical notes on Manchester and neighbourhood written for the occasion by Dr. E. M. Brockbank. The first article appeared on December 1st, 1928 (p. 1003), the second on January 26th, 1929 (p. 167), the third on April 27th (p. 781), and the fourth on June 8th (p. 1051).

MEDICAL EDUCATION IN MANCHESTER.

THIS subject is fully dealt with in the account of the facilities for education—primary, secondary, and university—in the cities of Manchester and Salford which is given in the *Book of Manchester and Salford* specially prepared for the meeting. A brief outline of the history of, and arrangements for, medical education may, however, be given here without, perhaps, detracting from the interest of the fuller account, especially as the University of Manchester was the first of the modern universities. The first event in the development of the Manchester Royal School of Medicine was the foundation of the Manchester Infirmary, as it was then called, in 1752. The medical students of the district until that time had received some years of their education from the physician or surgeon to whom they were apprenticed, and had to spend some months in London, Edinburgh, Glasgow, Aberdeen, or Dublin before they could qualify for examination by the licensing bodies of these towns. No lectures on medical subjects or demonstrations on anatomy were given outside London or south of the Border until about 1781. The conception and foundation of the infirmary is to be attributed on the medical side to Mr. Charles White. In 1757 the first rudiments of our hospital teaching appeared in the form of the admission of apprentices into the new infirmary to study the cases there. They were apprenticed for terms varying from two to seven years for a sum of thirty guineas, of which the surgeons received four. At later dates higher premiums were charged.

In 1781 there was founded in our city, mainly through the initiative of Dr. Thomas Percival, the Reverend Dr. Thomas Barnes, and Thomas Henry, F.R.S., with the support of Charles White, the Manchester Literary and Philosophical Society, which had for its object the "promotion of literature and science." It may be noted, in passing, that Percival and Barnes were born at Warrington, and that they and Henry were Unitarians, and it is also worthy of note that collegiate and university education in its earliest and, as will be seen later, in its final developments, was initiated by Nonconformity. In 1783 this society, chiefly through the initiative of Barnes, Percival, and Henry, fathered an institution which was really the beginning of collegiate or university education in the town. It was called "The College of Arts and Sciences in Manchester," and was designed for the instruction on very broad lines of those who, having finished the ordinary course of education, were about to engage in a commercial occupation. The prospectus then issued stated that lectures had already been given during the two previous winters, on anatomy and physiology by Mr. Charles White and his



THE MANCHESTER UNIVERSITY.

son Dr. Thomas White, and on chemistry by Mr. Thomas Henry. Owing to the fear that such education might unfit youth for ordinary business the institute declined, even from its first moments, and after two winters of unfavourable trial it was at length reluctantly abandoned.

Some of the early teachers of the medical students have left their mark for all time in the history of medicine. Charles White, the John Hunter of Manchester, was a great man, and much in advance of his contemporaries. Though practising general surgery he was more of a gynaecologist. He understood puerperal fever, and treated it on scientific lines, and he was the first man in England to recognize white leg as a definite morbid condition, which he called phlegmasia alba dolens puerperarum.

Dr. Thomas Percival was the founder of the principles of medical ethics, the Old Testament of professional conduct, and a pioneer in public health matters, especially as the new cotton factories affected it.

Thomas Henry was an apothecary and chemist, and has left his name in a preparation of magnesia which is still sold as Henry's magnesia.

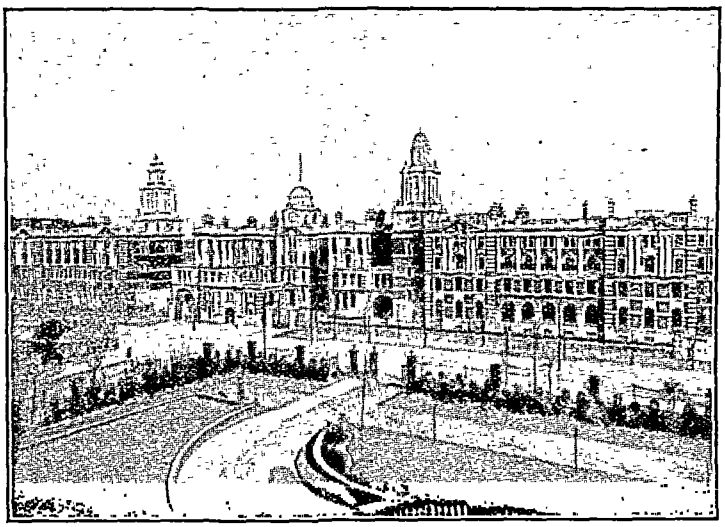
Dr. John Ferriar was the main force in getting a committee of public safety, or a board of health, formed to deal with fever epidemics in the town, and of opening a house of recovery, as they preferred to call a fever hospital in those days (circa 1796).

Peter Mark Roget, mathomatician, afterwards secretary of the Royal Society, taught physiology with the first printed syllabus of lectures. In what peaceful home nowadays are there no cross-words that cannot be smoothed out by Roget's *Thesaurus of Words and Phrases?*

Other relays of physicians and surgeons carried on the early torch of medical teaching, but the greatest credit must be given first to Joseph Jordan, and secondly to Thomas Turner, at the beginning of the last century, for being the real founders of a medical school proper in Manchester. Jordan began teaching dissection—on subjects of which he managed to get plenty by the methods described in the *Tale of Two Cities*, whilst other schools had but few—and included more systematic instruction than had to that date been given in other branches of the medical sciences. Jordan and Turner also forced the recognition of the school of medicine by the examining boards of London, and Turner and his colleagues secured for it the Royal patronage. In this way was the Manchester Royal School of Medicine founded. It flourished so much that various rival schools of ephemeral existence were started from time to time in the town, and finally in 1874 it joined forces with the Owens College, which had been founded in 1851 for general non-sectarian collegiate teaching, and which had barely escaped the fate of the College of Arts and Sciences of the previous century of dying of neglect and malnutrition. It was, however, saved chiefly by the enlightened and forceful care of its second principal, Professor Greenwood, and Henry Enfield Roscoe, the great chemist, and the Owens College, like so many feeble infants do, grew up into robust life. The union with the medical school greatly strengthened the college, and it attracted yearly an increasing number of students to its teaching. The next step was the formation of a university.

The Manchester University was the first of the group of English universities which were founded in the later nineteenth and early twentieth centuries. With the exception of Oxford, Cambridge, Durham, and London, all the universities of England conform to this new type. For six centuries Oxford and Cambridge held a monopoly of university education, but by the middle of the nineteenth century this was no longer possible. The two ancient Universities had catered for a certain well-defined class of the community, but the demand for education had become far more widespread. Oxford and Cambridge were still universities of the Anglican Church, fenced in by strict tests, but Nonconformity had greatly increased, not least in the North of England, and well-to-do Nonconformists were as anxious as Churchmen for the proper education of their sons. Moreover, for the north countrymen Oxford and Cambridge were difficult to reach and expensive to live in; nor did their scheme of studies take into account the conditions of the North.

Projects for a university of Manchester were in the air as early as the twenties and thirties of the last century, but the first effective step was taken by a private citizen, John Owens, who had an aversion to the religious tests imposed at the older universities. On his death in 1846 he bequeathed about £96,000 for the foundation of a college which would teach the subjects usual in universities to youths of the male sex. It was laid down as a fundamental principle that there were to be no religious tests. Legally, the college was a private trust, with absolute power in the hands of the trustees.



THE ROYAL INFIRMARY, MANCHESTER.

The Owens College, as it was called, was opened in 1851 in what was formerly a private residence in the town. After various vicissitudes and almost complete failure, the college became successful, and in 1873 was moved to the present site and to more commodious and better buildings. By the Acts of 1870 and 1871 the college was incorporated. It was now definitely a university college and received a new constitution. The admission of women was sanctioned.

Owens College, however, could not confer degrees; its students, if they wished to graduate, must sit for the examinations of London University. In 1875 a pamphlet was issued advocating the institution of a University of Manchester. But the Owens College was no longer the only university college in the North of England, and Manchester reluctantly consented to the institution of a federal university with constituent colleges, of which Manchester would only be the earliest. The title of the new university was to be the Victoria University, not the University of Manchester. University College, Liverpool, was admitted in 1884, and the Yorkshire College, Leeds, in 1887.

The first constitution of the University had great advantages. Freedom from the yoke of London had been secured; moreover, the admission of Liverpool and Leeds extended and encouraged university education. But there were also serious drawbacks. The staffs of the three colleges met together perhaps once a week on boards or committees; they had not the daily contact desirable for the staff of the same university. Each college had, naturally, its own policy and ambitions, and these could only be carried out by the consent and good will of the others, who might be indifferent or even antagonistic. Hence there was strife and friction. After twenty years a movement arose for the abandonment of the federal scheme and the institution of separate universities, and, in spite of considerable opposition, it was successful. In 1903 a university charter was

granted to Liverpool and a revised charter to Manchester, in 1904 to Leeds. The university founded in 1880 was still to continue in Manchester, but under the charter of 1903 it had received a new name—the Victoria University of Manchester—and a new constitution which secured its independent existence. Owens College closed its half-century of honourable activity by incorporation with the University in 1904.

The organization of the University teaching was based on faculties. In 1880, when the first charter was granted, there were three—arts, science, and law. Medicine was added in 1883, and other faculties—music, commerce, theology, technology, education—have subsequently been added.

All the necessary certificates of attendance for ordinary undergraduate clinical instruction have always been and must still be received at the Royal Infirmary, the present building having been erected on land provided by the University for convenience in teaching. In this way there is no difficulty for the dean of clinical instruction to keep an eye on the attendance of that certain proportion of students who are affected with "wanderlust" before its proper time. Courses of post-graduate instruction are arranged by the University at all the leading hospitals of the town.

The Manchester Royal Infirmary is a general hospital, which admits patients who are curable or capable of material relief, and who are not infectious. Children under 6 are not admitted unless urgently ill, nor are phthisis cases, except in acute stages, such as haemoptysis and pleurisy. Many early cases of phthisis naturally are diagnosed for the first time in the wards.

Students can be signed up for all necessary clinical work—medicine, surgery, "eyes, ears, throats, skins," pathology; all except fevers, midwifery, and mental and children's diseases by attendance at the Infirmary. The Eye Hospital, a branch of St. Mary's Hospitals, where students attend for instruction in diseases of children, the Public Health Laboratory, where instruction is given for the diploma in the subject, and the new pathological laboratories are all on the same plot of land, 400 yards square, as the Infirmary, and within two minutes' walk of each other, and five minutes from the University. The Radium Institute and the Christie Cancer Pavilion are also on the same plot of land, an aerial view of which was reproduced in the *Journal* of April 27th.

Midwifery is taught at the Maternity Branch of St. Mary's Hospitals, which is residential for students during their course of practical work. Students from other towns are attracted to the hospital by its very large practice, hospital and domiciliary.

The professors and lecturers of the medical school, in medicine, surgery, and their special departments, are, at the present time, almost without exception graduates of the University of Manchester in consulting practice. They are well acquainted with the conditions of medical work and the peculiar characteristics of the people in the neighbourhood, and therefore of the requirements of would-be practitioners. Whole-time professors of medicine and surgery have certain advantages, but are not the last word in preparing men for general practice.

The important function of a university—of research work, of searching for "what is hidden, what is lost beyond the ranges"—is encouraged to the fullest extent, and the degree of M.D. is generally obtained by original work, much of it carried out in laboratories. Fellowships of the Royal Society have been awarded to the heads of the anatomy and physiology departments for their scientific work. Several scholarships and fellowships are available to provide financial help for those students who are anxious to follow out some scientific problem or to work for their M.D. degree. Each student has to be signed up for dissection of the whole body, and there is no scarcity of subjects in the anatomical room to provide the necessary "parts" for this.

An important feature in the system of teaching anatomy and physiology in the school is to minimize the purely scientific aspect of these subjects and to pay great attention to their application to medicine and surgery with the help of x rays and instruments used in clinical investigation. The laboratory accommodation in these departments and in pharmacology has been considerably extended recently, and meets all the needs of the students. Applied physiology and anatomy courses, modified to meet the progress of the students in clinical knowledge, are given until the final year of study.

Instruction in mental diseases, as old Manchester students know, used to be received at Cheadle Royal Mental Hospital (a branch of the Royal Infirmary), and the lectures there were a great change and pleasant break from the "intramural" ones, and were much appreciated by students. This, however, is a registered mental hospital for private patients, and it was found that the visit of a score or two of students was objected to by relatives of patients. Instruction is therefore now received at the County Asylum, Prestwich, with its 1,000 and more patients, and the Cheshire County Asylum, Macclesfield; the students thus have every opportunity of studying what is one of the most important branches of general practice and one which has caused some alarming legal decisions in recent years.

Fevers are taught at the Corporation Hospital at Monsall with its 600 beds, and pulmonary tuberculosis at Baguley Sanatorium, also belonging to the Manchester Corporation, with its 300 beds.

When Sir William Osler was paying his last visit to Paris he wrote to me saying that the tendency in the medical schools there was to reduce academic lectures on the principles of this and that subject to a minimum and to get to the bedside as much as possible. He added that this was his own idea of the way to teach medicine and surgery. It is becoming more and more the tendency of British schools nowadays to adopt this plan, and a very great feature of the Manchester school is the clinical experience which students get of being taught from a variety of cases such as can hardly be seen in any similar teaching hospital. There are 600 beds in the Royal Infirmary, 280 in St. Mary's, and 148 in the Royal Eye Hospital.

At the Royal Infirmary there are so many beds that students, large as they are in number, have several allotted them for note-taking during their clinical instruction; they have thus every opportunity of learning on their own initiative to diagnose disease.

The dental school, with its own degree and diploma, is a very flourishing member of the medical school, and provides practical teaching at the Victoria Dental Hospital, which adjoins the University.

Women students are admitted to the medical school and to the hospitals for teaching purposes. The advantages and disadvantages of such mixed teaching are as many and various as the London schools have found.

CHANGES IN LONDON LOCAL GOVERNMENT.

NEW ADMINISTRATIVE SCHEME OF THE COUNTY COUNCIL.

THE first announcement of the character of the new administrative scheme for the County of London, in accordance with the Local Government Act, 1929, for discharging the functions transferred to the London County Council under that Act, is made in a report to the council for its meeting on July 9th by the special committee appointed, under the chairmanship of Sir Cyril Cobb, to deal with this important subject.

The special committee advises the council to declare that as soon as circumstances permit, all assistance which could, after April 1st next, be provided either by way of poor relief or by virtue of certain special Acts (hereafter mentioned) shall be provided exclusively under the appropriate Act, and not by way of poor relief. The special Acts in question and the transferred services to which they relate are as follows:

Maintenance and treatment of sick persons and pregnant women in hospitals. (Local Government Act, 1888, as extended by Section 14 of the Local Government Act, 1929.)

Maintenance of mental defectives in institutions. (Mental Deficiency Act, 1913.)

Maintenance of blind persons in institutions and in their homes. (Blind Persons Act, 1920.)

Maintenance and treatment of tuberculous persons in sanatoriums and other institutions. (Public Health (Tuberculosis) Act, 1921.)

Education of children. (Education Act, 1921.)

One noteworthy omission from this list is maternity and child welfare under the Act of 1918. It is pointed out that the position in London is complicated by the fact that under this Act the City corporation and the metropolitan borough councils are the authorities. The county council will, however, have responsibility in cases in which assistance is sought from the Poor Law, and it can also make arrangements with the other authorities for the provision of assistance either by way of poor relief or under the Act of 1918. But before any declaration is made in respect to this service the special committee thinks it necessary to ascertain whether the borough councils are in a position to undertake the functions in question and to provide the necessary accommodation at institutions other than Poor Law institutions. It is proposed to give further consideration to this matter at a later stage.

Transferred Institutions.

On the appointed day the county council will have under its control about 130 transferred institutions, these including the hospitals and other institutions of the Metropolitan Asylums Board and the hospitals or infirmaries of the boards of guardians, some of which already fulfil the functions of general hospitals. It is felt undesirable at present to earmark particular institutions for specified purposes. A complete survey will have to be made of the existing buildings and accommodation, and evidence obtained as to the requirements of the several classes of cases to be dealt with.

A Public Assistance Committee is to be set up to exercise the transferred functions in so far as they are not specifically referred to other committees of the council. It is proposed that this shall consist of 48 persons, 32 of whom shall be members of the county council. The county is to be divided into ten administrative areas, grouping together usually three, in one case four, and in two cases two contiguous metropolitan boroughs. Local committees, to act as subcommittees of the Public Assistance Committee, will be set up, each consisting of from 32 to 50 persons, and their duties will include the supervision and co-ordination of relief. There will also be district committees, for local detailed relief work; these will consist of eight or ten persons appointed by the local committee, partly from a panel including ex-members of Poor Law authorities and other persons versed in social work.

The Central Public Health Committee.

The transferred work with regard to provision for the reception and treatment of the sick will fall upon the Public Health Committee of the council, which will be reconstituted and designated the Central Public Health Committee. The proposals for its constitution have not yet been framed. It will deal with the provision, classification, maintenance, and management of hospitals other than mental hospitals, and for the purposes of hospital administration the county will be divided into five areas, each of which will be coterminous with the boundaries of a group of metropolitan boroughs, and co-ordinated with the (smaller) administrative areas proposed to be formed for the purpose of public assistance. It will be possible to make these same hospital areas suitable for the school medical service, thus enabling the Poor Law medical service, the public health organization of the metropolitan boroughs, and the school medical service to be co-ordinated in each area.

The scheme provides for "consultation and co-operation with voluntary hospitals and other hospitals serving the county," but the report adds that, having regard to the terms of the declaration proposed to be made by the council, it is not necessary to include detailed provisions dealing with this matter. As a preliminary to the formulation of any scheme for dealing with hospital accommodation in London a survey will be necessary. "In view of the magnitude of the task of reclassification and of the practical considerations which render it difficult for rapid progress to be made in this matter before the appointed day, it will be realized that the development of the scheme must necessarily be gradual. We have been in communication with the authorities representing the London voluntary and other hospitals, and have explained the position to them and intimated that we will at the appropriate time make arrangements for consultation with the joint committee appointed by the hospital authorities." Other duties which will come within the purview of the Central Public Health Committee will be the conveyance of cases to and from hospital, the periodical review of cases receiving hospital treatment, the provision of local medical services, laboratory services, medical instruction, and the training of nurses and midwives in connexion with hospitals, and the direction of the staff exclusively employed at hospitals, and of the district medical staff.

The Mental Hospitals Committee will be charged with the exercise of the transferred functions relating to the care of persons suffering from mental infirmity or defect. A clear dividing line between this field and that allocated to the Central Public Health Committee cannot be drawn, and the two committees will have to work in close co-operation.

It is added that the whole scheme must be regarded as provisional, and subject to review when practical experience has been gained.

A PHYSIOLOGICAL STUDY OF ASTHMA.

WHEN the conception of a disease is undergoing rapid change it is well, if only as a check on misdirected enthusiasm, to return occasionally to a study of those facts about its nature and pathogenesis which appear to be well founded and fundamental. Our readers were reminded a few weeks ago (May 18th, p. 930) by Mr. H. Mortimer Wharry of a paper by the late Professor T. G. Brodie and Professor W. E. Dixon on the pathology of asthma (published in the *Transactions of the Pathological Society of London* in 1903, vol. liv, pp. 17–39) in which they described a series of experimental findings which might well be correlated with those of investigations being carried out at the present day. Mr. Wharry suggested that it would be a great service to all who are interested in asthma if we could reprint this report, otherwise difficult of access, in the *Journal*. Having obtained Professor Dixon's consent we now publish the following abstract of the original paper.

ABSTRACT OF BRODIE AND DIXON'S PAPER.

The authors open with a brief discussion of the theories of the causation of asthma current at the time of writing. These were that asthma was due (1) to spasm of the bronchial muscles; (2) to a swelling of the bronchial mucous membrane; (3) to a special form of bronchiolitis; (4) to reflex spasm of inspiratory muscles.

The authors' view is that the condition is due to spasm of the bronchial muscles, and their paper is devoted to descriptions of the experimental work, and development of the arguments, in favour of it. Their method consisted in operations on the whole animal, sometimes anaesthetized, more frequently decerebrated. The chest was opened, a lobe of lung enclosed in a plethysmograph, and variations in its volume recorded. Artificial respiration was maintained by a mechanical pump, the stroke and speed of which was under accurate control; any variation in the volume of the portion of lung under observation could be due, therefore, only to one of two factors: (*a*) variations in its blood content, (*b*) variations in the condition of the passages by which the air reached the alveoli—that is, in the condition of the bronchioles. This followed from the fact that the pressure at which air reached the lung and the period for which this pressure was exerted were kept quite constant by the pump. In practice, the two factors are easily distinguished by inspection of the tracings.

Innervation of the Bronchial Muscles.

The first problem to be satisfactorily solved was that of the innervation of the bronchial muscles. Clearly, any stimulus which resulted in a diminution of the air passing into and out of the lung must have caused a contraction of the bronchial muscles, any that increased it, an inhibition.

Previous workers had established the fact that the motor nerve to the bronchial muscles was the vagus; this was readily confirmed. In the dog and rabbit, bronchial constriction is easily produced by vagus stimulation; in the cat, this effect is present, but is complicated by a preliminary dilatation. This result with cats suggested a search for broncho-dilator, as well as broncho-constrictor, fibres in the vagus. Since the muscles possess no normal tonus, an artificial tonic constriction was produced with muscarine or pilocarpine; vagus stimulation then produced marked dilatation; this apparent vagal effect was shown later by Dixon and Ransom to be due to the sympathetic nerves which are intimately associated with the vagus in the dog.

If the main accelerator nerves—that is, those which leave the sympathetic in the region of the ganglion stellatum—are tied and cut, and the ends connected with the lungs are excited by the faradic current, decided broncho-dilatation invariably ensues, provided that the bronchioles are in a state of some tonus. The dilatation is often maximal; it starts with the stimulation, gradually passes off to the former condition of tonus as soon as the stimulus is removed, and can be repeated an indefinite number of times. Electrical excitation of the cut peripheral ends of the first, second, third, and sometimes the fourth dorsal rami also produced a like effect. Broncho-dilatation was not obtained by stimulation of the rami when the accelerator nerves on the same side had been previously cut. Some of the fibres in the cervical sympathetic are broncho-dilator in nature and pass out by the accelerators.

The sympathetic fibres in the neck passing to the lungs are not confined to their own side, but may cross partly, or, in some cases, the experiments suggest, almost completely, to supply the bronchioles of the opposite lung. The way in which efferent fibres to the lungs come to be in the cervical sympathetic nerves, which are generally regarded as composed of fibres going to the head and neck region only, is uncertain. It seems likely that the broncho-dilator fibres reach the cervical sympathetic nerve high up in the region of the ganglion nodosum, but it has not been possible to trace the fibres. Another explanation has been suggested by Professor Langley—namely, that the phenomenon depends upon an axon reflex.

Investigations of Reflex Constriction.

Throughout many of the experiments, and especially in those designed to investigate reflex effects, very great difficulty was caused by the anaesthetic. Chloroform and ether both depress the medullary centres concerned with the effects to be studied; pithing clearly cannot be resorted to, since it would abolish the medulla altogether. The method finally adopted was to decerebrate the animal under as light anaesthesia as was practicable and then to let several hours elapse before going on with the experiment, in order to allow the effects of the anaesthetic to wear off. Even this was not completely satisfactory, which was the more unfortunate because of the importance of reflex effects in causing the asthmatic attack; many interesting results were, however, obtained.

Reflex bronchial constriction was never produced by exciting a cutaneous sensory nerve, or the stomach, or intestines. Slight constriction followed stimulation of the central end of the vagus, divided in the neck, or of the superior laryngeal. While no effect was obtained on exciting the cornea, bronchial constriction quite regularly followed stimuli, electrical, mechanical, or chemical, applied to the nasal mucous membrane. The best site for stimulation is the upper and posterior part of the nasal septum. The effects are gradual in onset, and last for a long period. They are immediately abolished on section of the vagi. The authors had little doubt that, could the difficulty of maintaining the medullary centres in normal condition have been surmounted, vigorous reflex effects could have been obtained.

The Action of Drugs.

The next point to be studied was the action of various drugs on the bronchial musculature. Three groups of effects could be produced: contraction, due to stimulation of vagal endings, contraction due to direct stimulation of muscle fibres, and relaxation due to paralysis of vagal endings. The first of these effects was produced by muscarine, pilocarpine, physostigmine, and digitaline; the second by gold salts, barium salts, and veratrine; the third by atropine, hyoscyamine, and hyoscine. Lobelia, used clinically for the treatment of asthma, produced an effect of transitory dilatation on muscles contracted, for instance, by muscarine; the effect recalled that of vagus stimulation in animal experiments. Morphine also relaxed the constricted muscles, but the dose was relatively high—higher, for instance, than that of lobelia. Finally, very marked effects were produced by CO_2, the action of which is chiefly, though not exclusively, on the medullary centres. CO_2 may restrict the air movements by one-half of their original amplitude.

Various Conflicting Theories.

In discussing their results, the authors point out that there is practical unanimity in attributing the asthmatic attack to diminution in the calibre of the bronchioles. The question narrows itself to a choice between muscular spasm, partial plugging of the vessels with secretion, or partial occlusion by turgid mucous membrane, as the immediate cause of the condition. The physical signs and the symptoms of an attack are not consistent with the theory of plugging of bronchioles by secretion—for example, there is frequently no expectoration, and though bronchitis is often present, it is usually clearly secondary in origin.

It is improbable that the bronchiolar mucous membrane becomes engorged, and so obstructs the airway, for in the first place it is thin, and possesses a relatively poor blood supply, while much of the nasal mucous membrane may be regarded practically as cavernous erectile tissue. In the second place, no engorgement of the lungs is produced. On the other hand, the rapid onset and termination of the asthmatic attack is perfectly consistent with the behaviour of the involuntary muscle; it can be induced by giving pilocarpine or muscarine, and cut short, instantaneously and completely, by a dose of atropine, or by sympathetic excitation.

The spasm theory of asthma is further strongly supported by a study of the drugs, used empirically, to treat the condition. Chloroform and ether have both been employed, and it has been found experimentally that it is impossible to produce constriction of bronchioles by vagal stimulation under chloroform or ether, since the nerve endings are paralysed by the concentrated doses of the vapour which they receive. All the drugs of the atropine series act similarly, producing complete relaxation of bronchial muscles, and all are highly esteemed in the treatment of asthma. In doses which completely paralyse the vagus, the blood pressure is lowered, and peripheral vessels are dilated; they would tend to produce some engorgement of the mucous membrane, but they would tend to stop secretion. Adrenaline, on the other hand, which is almost specific in the asthmatic attack, produces profound congestion of the whole pulmonary system. No evidence can be advanced to show that these drugs produce their action by diminishing engorgement of the mucous membrane. Morphine, which may be an invaluable drug in the treatment of asthma, has little or no peripheral effect in medicinal doses, but it is more valuable than any other drug in diminishing medullary reflexes, a fact made use of by every physician in the treatment of cough.

One reason why so many pathologists stress the vascular effect is on account of experiments made on the guinea-pig. The mucous membrane of the bronchioles in this animal differs from that in all others in that it is composed of a thick highly vascular membrane, which forms folds projecting into the lumen of the cavity. Anaphylaxis, when it occurs in higher animals (and it is so rare as to be of little importance in man), is mainly a vascular phenomenon; but in the guinea-pig it is accompanied by all the signs of acute asthma; this is mainly due to the turgescence of the mucous membrane, which may entirely block the lumen of the middle-sized bronchioles. Guinea-pig experiments, then, though interesting, have little value as evidence of what occurs in man. Nor is the evidence of the bronchoscope of much value, since all the surgeon can do is to observe the larger bronchi and bronchioles, and these have little power of contraction.

Alveolar Over-distension.

Over-distension of the chest is a striking and prominent symptom of an attack of asthma, and it must be taken into account in any theory of the cause of the condition. It can be

readily reproduced under conditions of the experiments described by varying, in the exposed lung, (1) the force of inflation, and (2) the time allowed for deflation.

Under experimental conditions, and with lung exposed and shut in a plethysmograph, the force which inflates the lung is provided by the pump; it is relatively great (100–120 mm. Hg) and it acts for a brief period; the force which deflates the organ is provided by the elasticity of the alveoli, and the lung tissue in general. It is relatively weak, but acts for a fairly long period. In a normal lung under these experimental conditions, over-distension is not produced, because the alveoli have ample time to empty themselves. It is, however, easy to produce over-distension by modifying the conditions in either of two directions. In the first place, if the period allowed for deflation is gradually decreased, clearly a time must come when the alveoli have only just emptied themselves before the next stroke of the pump again distends them. Any further shortening of the deflation time will result in a failure of the lungs completely to deflate themselves, and a permanent state of over-distension must result. In the second place, an increase in the force of inflation will lead to an increased distension of the alveoli. This, it is true, will tend also to increase the deflating force, but, since the lungs are not constructed of perfectly elastic material, the increase will not be proportional to the increase in the amount of air forced into the alveoli. Again, therefore, unless the time allowed for the deflation suffers a compensatory prolongation, inflation may again, so to speak, catch the tissue with its task of deflation unfinished.

If, to either of these experimentally produced conditions—shortened deflation time, or increased inflating force—there is superadded a constriction of the bronchioles, the condition is aggravated, and over-inflation at once produced, for the increased resistance to the passage of air clearly must tell most heavily against the weaker of the two forces—that of deflation. The pump overcomes the increased resistance fairly easily, but deflation cannot possibly be completed unless the time allowed for it is much prolonged; hence, as the tracings show, over-inflation is quite readily produced during vagus stimulation, or when the animal is under the influence of some drug such as pilocarpine or muscarine.

An explanation of the occurrence of over-distension in the intact animal, accompanying an asthmatic attack, obviously follows analogous lines. Here again the force of inflation—inspiration—is much more powerful than that of deflation—expiration. Both can be increased, but the former much more than the latter. During an asthmatic attack, therefore, the chest is necessarily over-distended, for the constriction of the bronchioles tells far more heavily against expiration than inspiration. It is a matter of observation, which has not been nearly sufficiently stressed by authors of textbooks, that the effort, during an asthmatic attack, is an inspiratory one; expiration is quiet and prolonged. The patient's efforts are directed to getting air into the lungs, not to getting it out. In most instances the description is that *respiration* is violent; it should be that *inspiration* is violent.

If it be granted that asthma is due to contraction of the bronchial muscles, it beomes important to decide how such contraction is produced. It may be peripheral, central, or reflex.

The Cause of the Bronchial Contraction.

For the following reasons either of the last two possibilities is more likely than the first: the attack is sudden in origin, and involves the whole of both lungs; only the one particular set of muscle fibres is involved, and attempts to produce an attack by the injection of sputum from asthma patients, or solutions of Charcot-Leyden crystals, have been unsuccessful.

If the origin of the contraction is central, then the question to be decided is whether the stimulus reaches the centre directly, or is relayed from some receptor surface or organ—that is, is reflex. It may be noted that CO_2 was found to give rise to bronchial constriction probably by direct action on the centre, since the effect is usually abolished by section of the vagi. CO_2 must accumulate in the blood during an attack, and must therefore tend to prolong its duration and to increase its severity. If, however, the cause of an attack were some direct irritation of the centre, it would be fair to expect a spread of the disturbance to other neighbouring centres, but this expectation is not fulfilled.

In favour of the "reflex" theory, on the other hand, there is much evidence, clinical and experimental. Asthma is known to be common in persons of a "nervous" habit. In persons subject to it, it is important to maintain the alimentary tract in a normal state, and attacks may be produced by an injudicious meal. It has been suggested that the sight alone, of certain animals, can produce an attack, and there is no doubt that, in some patients, the smell of certain animals can do so. There are fair grounds for believing that abnormal conditions of any part of the respiratory tract are of importance in predisposing to an attack, but it is clear that the nasal mucous membrane is of very direct importance in its causation. It has been mentioned that, experimentally, stimuli applied to the upper and posterior part of the nasal septum prove effective. Odours, and minute changes in the atmosphere, dust particles, etc., can excite an attack, while between asthma and hay fever there is known to exist a causal relationship. Operative treatment of the nose often gives a complete cure. Dr. Greville MacDonald reports most success when he could find and remove a growth on the inferior turbinate bone. Francis claims almost uniformly successful results after cauterizing the upper and posterior portion of the nasal septum.

With regard to the theory that asthma is due to a turgescence of the bronchial mucous membrane similar to that which can occur in the nose, it is remarked that there is no histological similarity whatever between the two tissues, and that direct experiment, where congestion of the lung was produced by ligating a pulmonary vein, never produced interference with the passage of air into and out of the lungs.

Australia.

[FROM OUR CORRESPONDENT IN VICTORIA.]

The Late Sir George Syme.

ON April 19th Sir George Syme, one of the leaders of the medical profession in Australia, died after a short illness. For many years, until his retirement from active practice, he had been one of the leading surgeons of Victoria, and it was in no small measure due to his efforts that the practice of surgery in this State was established on a sound footing. He had a long association with the Melbourne Hospital, and held successively the positions of out-patient surgeon, surgeon to in-patients, and, after his retirement from active hospital practice, consulting surgeon. He always took a keen interest in the welfare of the hospital, and performed invaluable services as a member, and later as president, of the hospital committee. Sir George Syme played a leading part in medical politics, was for many years a member of the council of the Victorian Branch of the *British Medical Association*, and also a past-president. Shortly before his death he presided at a meeting of the Federal Committee, and his conduct of the meeting was as direct and as skilful and his personal relations with the members as charming as ever. He was also President of the College of Surgeons of Australasia, and played a prominent part in founding it and framing its constitution. During the great war he volunteered for active service, and did very valuable work. His loss will be keenly felt, not only by the medical profession, but also by the community at large, and he will long be remembered for his ability, his nobility of character, and his high ideals of service.

Federal Council.

It is proposed by the Federal Committee of the British *Medical Association in Australia to establish a council*, incorporated under the Companies Act of one of the States, and to give the council powers similar to those possessed individually by those Branches in Australia that have taken advantage of the sanction to become corporate bodies. It is felt that the Federal Committee, having served a useful purpose for a period of eighteen years, lacks sufficient power to act effectively for all the Branches in Australia. It is thought that there will be no need for the Federal Council to meet frequently, as a good deal of the work will be delegated to committees and subcommittees, consisting of members residing in one city. The council would have

power to organize meetings of members, including congresses, conferences on special subjects, and meetings analogous to the Representative Meeting in the United Kingdom. It would also have power to encourage and promote research and post-graduate teaching. It would also be the recognized body to conduct negotiations with the Commonwealth Government on behalf of the Branches, and to consider matters affecting the British Medical Association in Australia as a whole.

Melbourne Chair of Anatomy.

Professor Frederic Wood Jones, D.Sc., M.B., F.R.S., has accepted the invitation of the council of the University of Melbourne to the chair of anatomy, in succession to Professor R. J. A. Berry. He will take up his duties in March, 1930. Professor Wood Jones held the chair of anatomy at the University of Adelaide from 1919 to 1926, when he was appointed to the Rockefeller Professorship of Physical Anthropology in the University of Hawaii, Honolulu.

Medical Visitors in Melbourne.

Mr. W. Sampson Handley paid a short visit to Melbourne on his way from the meeting of the College of Surgeons of Australasia. During his stay he visited some of the hospitals in Melbourne, and was entertained by members of the local Branch of the British Medical Association. Sir Charles Ballance is at present in Melbourne on a holiday visit.

Australasian Medical Congress.

The third session of the Australasian Medical Congress (British Medical Association) will be held in Sydney in the week beginning September 9th, 1929. Dr. G. Abbott was appointed president, on the nomination of the New South Wales Branch.

Scotland.

Aberdeen University.

AT the summer graduation at the University of Aberdeen on July 3rd, when a number of medical and other degrees were conferred, Principal Sir George Adam Smith commented on certain features of the past session. The total number of matriculated students was 1,385. The figure for men students had risen by 33, but there were 41 fewer women students. In the Faculty of Medicine there were increases in respect of both sexes; the total of 294 (263 men and 31 women) contrasted with 233 in 1927–28. The year had witnessed several notable additions to the medical and scientific resources of the city, with all of which the University was more or less associated. The new Hospital for Sick Children had been completed and opened upon its portion of the ample site acquired for the great Aberdeen Joint Hospitals scheme. The Principal added that it was fitting that they should congratulate Lord Provost Lewis on the success of his endeavour to raise £400,000 for the new Royal Infirmary, as well as on the honour recently conferred upon him by the King. In close connexion with the Rowett Institute for Research in Animal Nutrition, an Imperial Bureau was being founded which would be the centre for recording and classifying researches in that subject and their results throughout the British Empire. Again, in addition to the Aberdeen Laboratory of the Scottish Fishery Board, the National Department of Scientific and Industrial Research was to open another laboratory, which would enlist the co-operation of different University departments such as that of bacteriology; it was confidently hoped that this new development would be of benefit to the science of ichthyology as well as to the fishing industry of the country. Lastly, the Scottish Department of Agriculture had arranged to establish in Aberdeen an institute of soil research; this would be named the Macaulay Research Institute in recognition of the munificence of the distinguished Canadian, a native of Aberdeenshire, who had rendered its establishment possible. In all of these directions Aberdeen and the North of Scotland were to be congratulated upon the increase of their scientific and educational facilities.

The Health of Edinburgh in 1928.

In the recently published annual report for 1928 of the Public Health Department of Edinburgh, the medical officer of health, Dr. William Robertson, regards the death rate of 13.7 per 1,000 as satisfactory, but points out that the birth rate of 17.3 is the lowest yet recorded, except for the years 1917 and 1918. In 1861 the figure was 33.4. With such a low birth rate prevailing he thinks it is reassuring to find that the infantile mortality figure for 1928, of 75 per 1,000 births, is a record for the city. The mortality figures would undoubtedly be still more satisfactory if it had been possible to expedite the slum clearance schemes. Year after year the worst figures have been recorded for those wards in which there are the largest number of single and two-roomed houses. St. Giles's ward, with 1,142 single and 1,694 two-roomed dwellings, mostly in tenement houses, had a death rate of 18.5 in 1928, and an infant mortality rate which was considerably higher than that of any other ward in the city. Dr. Robertson remarks that the slum clearance problem in Scotland differs from that in England, where the old style of tenement house, with its long dark passages, gloomy ill-ventilated lobbies, and centrally placed stairways is virtually non-existent. Reconditioning of these houses, in itself an expensive matter, might make them suitable for a certain class of tenant, but they always remained unfavourable for growing children. Dr. Robertson adds that it must not be thought, however, that the housing policy of the corporation had not been progressive: in the present century more than 5,000 houses had been closed and most of their inmates had been transferred to new houses in the Lochend, Prestonfield, Corstorphine, and other outlying districts, with notable improvement in the health and habits of the persons concerned. Reference is made in the report to the development in connexion with the maternity and child welfare service and of cookery classes for working-class mothers. Every effort has been made to render these classes practical, the demonstrations being given on open fireplaces and with the most elementary appliances. Instruction was supplied in food values and in the necessity of including in the dietary simple foods containing certain vital elements essential for health. The value of good milk was especially stressed. These classes were proving very popular. Dr. Robertson considers, therefore, that a great deal is being done to try to ensure that the poorer children shall have a sufficiency of fresh air, adequate space for exercise, and well-balanced dietary; as a result they were growing up better able to resist disease. It had long been felt that there was a lack of hostels for both men and women in the city, where good food, clean beds, and comfortable surroundings would be available at a low cost; plans for these were now taking definite shape. The tuberculosis notifications and the deaths from pulmonary tuberculosis were the lowest that had been recorded. Since the beginning of the century there had been a fall of over 50 per cent. in the deaths from tuberculosis of the lungs. Scarlet fever accounted for only eight deaths during the year, and the death rate from diphtheria was the lowest since 1912. The venereal disease scheme continued to prove highly successful, but Dr. David Lees again deplored the inability of his department to compel patients to complete their cure. The problem of rheumatism in young persons is giving the health authorities much concern. A very complete inquiry into dermatitis as it affects bakers has been made. The bacteriology of the water of the municipal swimming baths was in course of investigation by Dr. Grierson, and recommendations would be submitted to the committee responsible for the control of the baths in the city.

The Royal Victoria Hospital Tuberculosis Trust.

Under the title of "The white plague in Scotland—how it is being vanquished," a report has been published on the work during the past year of the Royal Victoria Hospital Tuberculosis Trust. Since the Victoria Dispensary was opened in November, 1887—the first of its kind—the dispensary scheme of Sir Robert Philip has been extensively developed, and, in Edinburgh, its birthplace, there has been established a sanatorium (the Royal Victoria

Hospital); a tuberculosis school; a working colony; a sanatorium colony (at Southfield); a tubercle-free dairy farm; and the chair of tuberculosis in the University. Some details of the work of the trust are given in the report, and the increasing tendency to admit young children with tuberculosis to the Southfield Sanatorium is welcomed. It is mentioned that there is no limit to the duration of treatment in this institution provided that there is any possibility of a successful issue. In the laboratory there an investigation of the standardization of tuberculin has been in progress in collaboration with the laboratory of the Royal College of Physicians of Edinburgh, and a method has been evolved which appears to be readily applicable. An appeal is made in the report for an additional sum in donations of £600 a year to enable the committee of the trust to appoint two more research workers.

England and Wales.

Combined Meeting of the British and American Orthopaedic Associations.

THE combined meeting in London of the British and American Orthopaedic Associations (to which reference is made at page 62) reached its culminating point on the social side on the night of July 5th, when nearly every member of the two associations attended the dinner at the Café Royal, Regent Street. An informal reception preceded the dinner, at which many prominent British and American representatives of orthopaedic surgery were to be seen in animated conversation. It is to be presumed that such conversations were not necessarily all of a scientific nature, but were many of them of the type which would indicate that fellowship and good feeling between English and American orthopaedic surgeons are happily cemented. The dinner which followed the reception was an outstanding success, and, though the programme provided for a certain number of formal speeches, the happy atmosphere of internationality was responsible for several delightful impromptu speeches in addition to those on the programme. The toast of "The King" was proposed by Sir Robert Jones, who presided over the gathering, and was honoured in silence. Dr. Goldthwait of Boston, in response to a request from the chairman, referred to a war-time telegram which had been responsible for twenty American orthopaedic surgeons being sent to join the British Forces in 1917. This cable was the beginning of the happy association between American and British orthopaedic surgeons which found expression in the present gathering in London. Sir Robert Jones referred in the happiest vein to the great services rendered by King Manoel of Portugal in the training of war cripples. King Manoel had, in spite of great difficulties, been able to arrange to come to the dinner, and was sitting on Sir Robert's right hand. After many pleasant allusions to the orthopaedic work during the war, Sir Robert proposed his Majesty's health, which was drunk with great enthusiasm. King Manoel, in his reply, made witty reference to his association with Sir Robert Jones and other distinguished American and British orthopaedic surgeons during and after the war. He touched a deeper note in speaking of their general experience in the treatment and after-care of the wounded and maimed. Professor Hey Groves proposed the health of "The American Orthopaedic Association" in a short and effective speech, and the toast was accorded musical honours. In replying to this toast, and in proposing the health of "The British Orthopaedic Association," Dr. Albee expressed his gratitude for the warm welcome they had received and the interesting programme which had been provided. This toast in its turn was accorded with musical honours by the American members present. Sir Robert Jones proposed the health of "The Guests," making particular reference to the good fortune of the orthopaedic associations in welcoming Professors Putti and Calvé, and further in obtaining a communication from Professor Putti. Sir Squire Sprigge replied very gracefully on behalf of the guests. The last speech was by Dr. Goldthwait, who proposed the health of the chairman, and Sir Robert Jones's health was drunk with great enthusiasm. During the intervals between the speeches Dr. Rugh greatly entertained the gathering by singing plantation songs at the piano.

Presentation to Dr. William Collier of Oxford.

An event of considerable interest to the medical profession in Oxford and district took place on July 1st when, by the courtesy of the Rector and Fellows of Exeter College, Dr. William Collier was entertained at dinner in the College Hall in commemoration of the fiftieth anniversary of his arrival in Oxford; about one hundred local practitioners and their wives were present. Advantage was taken of the occasion to present Dr. Collier with his portrait painted by the Hon. John Collier, representing him in his Cambridge M.D. gown, as a token of esteem and affection from his many friends and colleagues in and around Oxford. The ceremony was presided over by Dr. Cheatle of Burford, who laid stress on Dr. Collier's high sense of professional honour and benevolence towards the less fortunate members of the profession. He referred also to the extremely valuable work of Dr. Collier in connexion with the administrative side of the Radcliffe Infirmary as distinguished from his medical services. Dr. Collier, though a very busy man, had found time to serve his fellow citizens for a long period in the deliberations of the local authority. In conclusion, Dr. Cheatle paid a warm tribute to the practical efficiency and personal charm of Mrs. Collier. Sir Thomas Legge said that there were few now who could remember Dr. Collier's advent into Oxford as house-physician to the Radcliffe Infirmary, fresh from his success in the running field and on the bicycle path at Cambridge. After leaving the Radcliffe Infirmary he started practice in the High Street, but he subsequently returned to the Infirmary as physician, and the interests of that great institution and the causes affecting the honour, welfare, and glory of the profession, especially through the British Medical Association, became an absorbing influence on the remainder of his life. The development of the Oxford Medical School was the subject of Dr. Collier's presidential address to the Annual Meeting of the British Medical Association when it met in Oxford in 1904. Dr. Collier, in a cheerful and reminiscent vein, thanked the gathering and other subscribers for the honour they had conferred on him, and touched on the many changes that had taken place in private and hospital practice during the past fifty years. The arrangements for the dinner were admirably carried out by Dr. F. G. Hobson and the staff of Exeter College.

The New Middlesex Hospital.

Middlesex Hospital now presents one of the most anomalous architectural spectacles in London, for in contrast with the long familiar central portion and the east wing with their dilapidated appearance, the new west wing is a huge structure, doubling the height of its fellow, and of an impressive and pleasing design. This new wing is expected to be ready to receive patients in three months' time. The ground floor, which is to be used for administrative purposes, contains also an operating theatre. Each of the next four floors is arranged on an identical plan, with two main and two side wards, providing thirty-seven beds in each unit. The fifth floor is a gynaecological unit with twenty-four beds and a complete operating theatre suite. On the top floor is the children's ward, the gift of Mr. Bernard Baron, with wall tiles arranged as coloured pictures, and an adjoining roof playground from which there is a view across London to the country beyond. The floors of the wards are composed of marble terrazzo, and most of the internal joinery is of hard wood. The walls are tiled up to the ceilings, and the floors meet the walls in a curve. Every ward is heated by electric fires, and over every bed is an electric lamp and a wireless headphone. The walls of the operating theatre are glazed with a green-tinted plate glass, specially chosen for the protection of the eyesight of those operating, and all the appliances are chromium-plated. Some figures have been furnished with regard to the materials used in the construction of this building, from which it appears that about 1,000 tons of

steelwork have been used, together with 200 tons of reinforcing steel rods; 1,200 tons of sand and ballast; 2,000 tons of Portland cement, and one and a half million bricks. Sanitary towers have been constructed at the north and south ends of the building, carrying from the basement to the roof. There are four balconies, which may be used for open-air treatment. At a luncheon which preceded the press view of the new structure on July 4th, Sir Herbert Morgan, chairman of the appeal committee, announced that of the sum, exceeding £1,000,000, which was required for the execution of the entire scheme, more than £600,000 had been collected; the response to the new appeal which had been launched showed that the generosity of the public towards Middlesex was not abating. Mr. A. E. Webb-Johnson, surgeon to the hospital, said that after the completion of this new wing the demolition of all that remained of the old building would begin, and in its place would rise the most complete and up-to-date hospital in London. He referred with justifiable pride to the achievement of the Middlesex Hospital in rebuilding its wards without evacuating its site, closing a bed, or curtailing a service. Lord Leitrim emphasized the indebtness of places outside London to the Middlesex Hospital for taking patients with whom the local hospitals could not deal, and also for its great work as a research and training centre.

University College, London.

An assembly of faculties was held at University College, London, on July 4th, when Sir Walter Fletcher, secretary of the Medical Research Council, and special visitor to the College, distributed the awards to the scholars, prizemen, and medallists for the year, and briefly addressed the gathering. The annual report of the College, presented by Sir Gregory Foster, the provost, after a regretful reference to the passing of Lord Rosebery, who had held the office of Chancellor of the University for twenty-seven years, stated that the centenary fund now stood at £222,798, which was well on the way towards half the sum required. The College was still in search of a benefactor who would provide £120,000, and thus secure the single generous offer of a like sum for the building, equipment, and endowment of the department of zoology and comparative anatomy. The new building for this department is to be in Gower Street, immediately to the south of the anatomy block of the Faculty of Medical Sciences buildings. Sir Gregory Foster mentioned some important extensions which had taken place during the past session. The department of municipal engineering and hygiene had been provided with a new laboratory, and better accommodation had been afforded for the School of Librarianship, also lecture rooms for the Faculty of Arts. The new University observatory at Mill Hill Park is to be opened in October by the Astronomer-Royal. It is hoped next session to possess an exhibition room for the display of the valuable and expanding collection of etchings and prints which have been bequeathed to the College; one of the latest additions is a gift by Lady Godlee, in memory of her husband, the late Sir Rickman Godlee. Sir Gregory Foster added that the number of students on the College books was 3,175, as compared with 3,054 last session; 1,850 of them were full-time students, and 498 were doing post-graduate and research work. At the conclusion of the formal proceedings, the company, which included the Greek Minister, the High Commissioner for India, and many distinguished friends of the College, listened to a concert by the students, and afterwards inspected the new anatomy and physiology building, the gift of the Rockefeller Foundation, and other extensions. Sir Flinders Petrie's exhibition of the results of recent discoveries of the British School of Archaeology in Egypt aroused much interest; he has unearthed the remains of fortified "cities" in Southern Palestine which throw some illustrative light upon the Old Testament narrative. One little circumstance of Assembly Day which was noted was the wearing by the chairman of the College committee, Viscount Chelmsford, of the memorial ring (recently purchased by the College) of Jeremy Bentham, whose skeleton, dressed in Bentham's accustomed garb, is a College possession.

Correspondence.

LAVAGE IN PLEURITIC EFFUSION.

SIR,—In the discussion on the treatment of pleuritic effusion, to be held at the Annual Meeting of the Association at Manchester on July 25th, I hope that attention will be devoted to the danger of pleural lavage, and some conclusion be arrived at as to its real extent.

It used to be laid down that the proceeding was dangerous; lately the most divergent views have been expressed; here are two of them: (1) "If simple drainage is ineffectual, irrigation should be resorted to as a routine" (Grant Massie, *Recent Advances in Surgery*, 1928, p. 202); (2) "The pleura should not be washed out with antiseptic solutions, as this has, in a number of cases, caused death from shock" (Geoffrey Marshall, *Conybeare's Textbook of Medicine*, 1929, p. 493).

That danger exists the following case makes clear. It occurred some thirty-five years ago; unfortunately I could not publish it at the time as it was not my case, and its publication then would have thrown discredit on the colleague in charge of it. He is long since dead, and therefore many details have been lost, such as the side affected, the exact size of the cavity irrigated, the antiseptic used; but the main facts are indelibly impressed on my mind. Briefly they were these. The patient being irrigated died quickly (I was told) with all the symptoms of a rapidly fatal haemorrhage. At the necropsy (which I made) there was no haemorrhage, but the abdominal organs were engorged with blood to an extent which I have never seen in any other case; they literally dripped with blood like full sponges. It seemed to me that, in some way or other, the irrigation had "opened the splanchnic floodgates" and that the patient had bled to death into his own abdominal organs.

The question which ought to be settled is whether such a disaster is so extremely rare as to be negligible, as the first quotation suggests, or sufficiently common to justify the second quotation. The matter is much too serious to be left in so much doubt. It would also be well to know if side, size of cavity, or antiseptic used affects the risk.

I am sorry that it is impossible for me to be present at the Manchester Meeting.—I am, etc.,

Exeter, July 8th. W. GORDON.

RADIUM TREATMENT OF MALIGNANT DISEASE.

SIR,—May I be allowed to call attention to some points which appear to be not quite clear, and to correct some mistakes that have occurred, in the otherwise excellent summary to my Cavendish Lecture of June 21st, which you have been pleased to publish in your columns (June 29th, p. 1164).

As regards uterine cancers, no one (and perhaps least of all myself) considers as completely cured patients treated only two years previously. Lack of time prevented me from commenting as fully as I would have wished on the tables of statistics exhibited. Our patients treated in 1926 who, on examination at the end of 1928, presented neither signs nor symptoms of cancer were considered as "clinically or provisionally cured"; only those patients treated from 1919 to 1923 who had passed the five years' observation point were considered "cured." Among the patients treated during the years 1924–26 there will occur several cases of recurrence before all have reached the five years' observation point, and these cases will thus lower the proportion of cure for those years. I added that in cases at the limit of operability, and especially in inoperable cases, cure was sought in a combination of internal curietherapy with either roentgenotherapy or transpelvic curietherapy.

Following the remarks on the treatment of cancers of the superior maxilla by resection and the packing of radium tubes against the walls in the resulting cavity, your report states that in the cases of cancers of the tongue and floor of the mouth "the method adopted was again that of weak foci, the tubes being retained by gauze packing."

This latter statement is incorrect. The treatment is by radium puncture in the cases of carcinoma linguae, and by radium puncture often preceded or followed by the action of a surface moulded applicator in the cases of cancers of the floor of the mouth; but in no case are the tubes retained in position by gauze packing in cancers of these localizations, as is necessary in cancers of the superior maxilla. We are by no means opposed to the radium-surgical procedures, which give good results in a limited sphere of applicability.

Discussing telecurietherapy, I mentioned the necessity of protecting the body of the patient and neighbouring persons by surrounding the source of radiation with several centimetres (6 cm. actually), not inches, of lead. And, finally, a slip has been made in substituting screen distance for skin distance (that is, distance from the radiating surface to the skin) in the same paragraph.—I am, etc.,

Institut du Radium, Paris, July 3rd. C. REGAUD.

MEDICAL PRACTICE IN THE INTERNATIONAL SETTLEMENT OF SHANGHAI.

SIR,—The contribution on scientific medicine in China from "An Occasional Correspondent" (April 13th, p. 699) conveys an erroneous impression of the status of foreign medical practitioners in the International Settlement of Shanghai.

A brief statement of the facts will make the position clear. At the present time there are 171 medical practitioners of the following nationalities in the International Settlement, whose names are on the official list of the Public Health Department.

Japanese	55	German	11
British	28	Austrian	5
Russian	22	Hungarian	2
American	19	Polish	2
Chinese	14	Belgian	1
French	11	Czechoslovakian ...	1

There is no compulsory registration of medical practitioners in the Settlement, but before admission is granted to practise in the municipal, general, and country hospitals, and before certificates are accepted by the municipal council, medical practitioners must be attested by their respective consular authorities, and must present satisfactory credentials to the Municipal Public Health Department. Those, other than Chinese, who have no consular representation are required to pass a medical board formed by three medical men nominated by the Municipal Council of the International Settlement, the Provisional Commission of Municipal Administration of the French Concession, and the Board of Governors of the General Hospital.

The Land Regulations and Annexed By-laws by which the International Settlement is governed have very little bearing on public health, and make no provision for the compulsory registration of medical practitioners. From time to time since 1902 attempts have been made to obtain such powers as part of comprehensive public health legislation, yet for various political reasons the attempts have not been successful. In 1926 the Municipal Council of the International Settlement approved of a scheme of voluntary registration of medical practitioners, dentists, and veterinary surgeons with a view to controlling the sale of poisons and noxious drugs within the Settlement. Draft regulations were submitted to the principal national medical societies, but on account of conflicting national views and interests negotiations were not concluded until November, 1928. The scheme now only awaits the co-operation of the French municipal authorities before being put into effect.—I am, etc.,

Shanghai, June 17th. C. NOËL DAVIS, Commissioner of Public Health.

TREATMENT OF EXOPHTHALMIC GOITRE.

SIR,—After a careful perusal of Dr. Douglas Webster's letter (June 29th, p. 1179) criticizing a part of my conclusions on the treatment of exophthalmic goitre, it seems to me that he has not fully appreciated the essential point of my contribution. I have taken the basal metabolic rate, weight, and pulse as the essential standards of progress of amelioration or of failure. Unless one has some such standard of accuracy it is indeed extremely difficult or impossible to gauge the effect of any treatment. The literature of exophthalmic goitre is only too full of examples in which the term "cure" is used without any convincing proof that a cure has actually been obtained. I am afraid that the radiologists in this country have not sinned the least in this direction. I have been through the literature and am perfectly well acquainted with the papers to which Dr. Webster refers. I omitted reference to them because the cases were not in my opinion sufficiently completely investigated. One needs in scientific medicine instruments and methods of precision, and these are apt to upset the perfectly honest yet often inaccurate conclusion of the clinician who relies on the older methods, good enough it is true for many diseases, but apt to lead us astray in so complex a disease as exophthalmic goitre.

I have been at very great pains to check the results of the *x*-ray treatment, and all the patients undergoing that treatment were readmitted to hospital at intervals to check their progress. It was manifestly impossible to keep them in hospital for the whole twelve months of their treatment. I was quite prepared to find that *x*-ray therapy was curing the condition in the 80 per cent. of cases that has been claimed, but my results did not fulfil this expectation. Nor were these cases specially selected or particularly bad ones. They form a series that runs more or less parallel with the operated ones, save that one case only had been rejected by the surgeon, and this patient died even after *x*-ray therapy.

I find that I was misinformed as to the dosage, which should have been half an erythematous dose. Perhaps Dr. Webster will pardon me for a mistake which was not entirely my own.—I am, etc.,

Manchester, July 2nd. CHARLES S. D. DON.

GAS-OXYGEN ANAESTHESIA.

SIR,—The experience of Dr. T. de Lacy Walker (June 29th, p. 1180) has been different from my own. It is rare for me to come across any student who has been taught gas-oxygen anaesthesia at all—either with Boyle's or any other apparatus. They have been taught semi-open ether or C.E. in England and chloroform in Scotland.

I can say that he admits my contention that Boyle's apparatus is used chiefly in conjunction with other. This is necessary, because the control of the gases is so erratic. There are other points, too, besides control, about an efficient machine, which appeal to me, and probably would to Dr. Walker. One is an emergency oxygen valve, whereby, if a patient stops breathing from any cause, oxygen under pressure can be forced into the lungs, thereby doing the most efficient artificial respiration possible. As deaths under nitrous oxide gas occur almost wholly from asphyxia only, they may be prevented if oxygen can be forced in independently of the patient's own effort; I have seen patients who appeared to be dead restored by this means in a few seconds.

Dr. Walker entirely agrees with my plea for the more general use of gas and oxygen, but this cannot come about without a more efficient gas control than there is in Boyle's apparatus. What I mean is conveyed in the following extracts from letters I have recently received: "I quite agree with your statements of the difficulty of using Boyle's apparatus; but this is the only one I have seen." Another says: "We have a Boyle's bubble bottle apparatus, but I must confess I cannot do much with it—so much so that I have practically given up using it." Evidently I am not alone in my opinion.

With regard to the rest of Dr. Walker's letter, it is generally agreed that nitrous oxide and oxygen is the least toxic of any anaesthetic we know of at the present time. It is selected for bad risks such as diabotics, and toxic and nearly moribund intestinal obstruction cases, even by surgeons who would not consider using it for anything else. Surely if it is good for these it should be satisfactory for others. In fact, the comfort of all patients is so much enhanced by its use that I am of the opinion that the only contraindications are ignorance and lack of efficient apparatus. May I, in concluding, add the three following

generalizations: (1) careful selection of cases is not very necessary, as already the very worst are passed on to it; (2) any apparatus requires keeping in perfect working order to secure efficient working; (3) no man who gives gas-oxygen anaesthesia can afford to go to sleep on the job.—I am, etc.,

Doncaster, July 4th. E. J. CHAMBERS.

CONSULTATIVE COMMITTEES UNDER THE LOCAL GOVERNMENT ACT.

SIR,—It appears to me important that action taken in regard to the constitution of the Consultative Committees under Section 13 of the Local Government Act should be reported. I therefore send you the following facts for the information of your readers.

In Liverpool the Consultative Committee has been appointed, and consists of twelve members, six representing the governing bodies of the voluntary hospital and six representing the medical and surgical staffs. The six medical representatives have been nominated by the Liverpool Hospital Staffs Association, a body which includes in its membership all those who are on the staffs of the local voluntary hospitals.

In Lancashire the Consultative Committee has also already been constituted. It is to consist of one lay and one medical representative from each of the voluntary hospitals in the county area; the medical representatives have in each case been nominated by the medical board of the hospital concerned.

Several of the neighbouring county boroughs have elected their Consultative Councils on the same lines as those followed in Liverpool. A conference to constitute the Consultative Committee for the county of Cheshire is shortly to be held.—I am, etc.,

Liverpool, July 8th. K. W. MONSARRAT.

MEDICAL ATTENDANCE ON PATIENTS IN PRIVATE WARDS OF HOSPITALS.

SIR,—In your issue of June 29th (p. 1181) Dr. R. H. Dix comments on the proposed policy for the above-mentioned patients as outlined on page 127 of the *Supplement* for April 20th in Section XI, paragraph 29. He states that "hitherto the policy of the Association has granted to these people complete freedom of choice of medical attendant"; and that "the new policy deprives them of this right."

Up to the present the British Medical Association has had no policy at all with regard to these patients. It would seem that Dr. Dix is confusing with this group those in nursing homes or annexes attached to hospitals, for whom a quite different policy is outlined in the following section (XII). The time is so pregnant with far-extending changes in the relationship between State and voluntary hospitals and their effect on medicine and private practice that it is to be earnestly hoped that everyone will fully acquaint himself with what is going on and assist in formulating an equitable policy.—I am, etc.,

Hove, July 6th. E. ROWLAND FOTHERGILL.

PRURITUS ANI.

SIR,—In his article on the treatment of pruritus ani (June 15th, p. 1070) Mr. Gabriel did not mention the use of ultra-violet rays in the treatment of this intractable condition. I have had some satisfactory results with ultra-violet rays after many forms of treatment have been tried, including x-ray radiation. For some little time now I have been using an electrode which contains titanium, and I consider that the results are quicker and better with this metal than with tungsten. In hospital, the cases under me have been treated by the tungsten arc, and the results have been very satisfactory, but in private I have used the titanium arc with more rapid success. The treatment should be given daily, and I have found that natural sleep is forthcoming after comparatively few administrations. With pruritus vulvae the results are equally gratifying.—I am, etc.,

E. G. FRENCH, M.D., M.R.C.P.,
Physician in charge of the Skin Department, London Temperance Hospital.

July 2nd.

DIFFICULT LABOUR.

SIR,—Professor R. W. Johnstone's British Medical Association Lecture on difficult labour, published in your issue of June 22nd (p. 1105), reminds me of a case of non-rotated occipito-posterior presentation I treated some years ago. The head had come low down without rotation, and it occurred to me that by inserting one blade of the forceps behind it might be possible to lever it forward. I did this, and, taking great care not to use much pressure on the soft parts, I found it quite easy to rotate the head, and inflicted no injury in doing so. I may mention that I did not rotate the shoulders at the same time, and the child was born alive.

May I also mention a simple method of using a gum-elastic catheter for reducing the prolapsed cord? The books mention passing a tape or thread down the lumen of the catheter before looping it round the cord. It is far easier to bring the stilette out through the eye of the catheter, loop the thread round it, and reinsert the point within the catheter. When the cord has been replaced withdrawal of a couple of inches of the stilette releases it, and the tape is born with the placenta.—I am, etc.,

Wokingham, July 1st. F. R. HUMPHREYS.

DEFINITION OF RHEUMATOID ARTHRITIS.

SIR,—I wish to endorse the statement implied in the sentence "there are present signs of a general disturbance," in the third paragraph of Dr. Neligan's letter published in the *British Medical Journal* of July 6th (p. 32). Examples are the frequently associated colitis on the one hand and the liver disturbance on the other. Of these two I regard the liver as the more guilty.—I am, etc.,

Arnside, July 6th. D. M. MACDONALD.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examination indicated:

FINAL B.M., B.CH.—H. H. Aitchison, G. Campbell, B. R. Caygill, J. A. Eyres, C. R. Greene, H. E. Mansell, J. C. Nicholson, M. G. Pearson, J. W. de W. G. Thornton, W. J. Walter. *Forensic Medicine and Public Health:* H. S. Atkinson, J. M. Gibson, T. N. Gledhill, H. M. Harris, R. S. Harrison, J. M. Lees, A. J. M. Melly, C. N. Milner, A. Secker-Walker, W. B. Williams, Annie D. M. Adams. *Pathology:* F. Bicknell, J. B. Bishop, J. R. Braybrooks, W. D. T. Brunyate, F. E. Buckland, E. C. Coaker, C. M. Duncan, D. G. Ferriman, J. H. Hunt, W. E. S. Merrett, C. N. Milner, R. D. Newton, W. R. Pullinger, [illegible] O. J. Vaughan-Jackson, [illegible] rcer. *Materia Medica:* [illegible] ckland, H. W. Davies, [illegible] y, M. A. Hatt, G. W. Hinchliff, H. de B. Kempthorne, R. M. Marshall, N. C. Parfit, N. L. Rusby, J. A. Scott, R. F. Woolmer, C. H. Yeoh.

UNIVERSITY OF LONDON.

AT a meeting of the Senate of the University of London, held on July 3rd, Dr. E. Graham Little, M.P., was elected as a representative of the Senate upon the Court, and was re-elected for the seventh time as chairman of the Council for External Students.

Sir Gregory Foster, B.A., Ph.D., has been elected Vice-Chancellor for the year 1929–30, and the Rev. John Scott Lidgett, D.D., M.A., Deputy Vice-Chancellor for the same period.

LONDON HOSPITAL MEDICAL COLLEGE.

The Freedom Research Entrance Scholarship in Pathology, value £100, open to students of the Universities of Oxford and Cambridge, has been awarded to Mr. J. F. Brock of University College, Oxford.

UNIVERSITY OF DURHAM.

AT the convocation held on June 27th the following medical degrees and diplomas were conferred:

M.D.—M. Coll, O. C. Dobson, J. Hare, A. H. Holmes, F. W. Marshall, P. M. Rivaz, Gladys Stableforth, A. J. Watson, R. Wear.

M.B., B.S.—S. Adler, J. C. Arthur, W. F. Cross, K. Daniels, C. E. Goldberg, H. W. T. Hall, W. Hall, J. Maddison, H. D. Ord, A. R. D. Pattison, J. K. H. Scott, J. B. Tilley, Nora Walkinshaw.

B.Hy., D.P.H.—Katherine M. Cellan-Jones, O. C. Dobson, A. J. Watson.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

M.D.—Helen M. Duvall, W. H. Evans, W. M. Frazer, L. S. Goldman, [illegible]

M.B [illegible] ndlay, [1234] T. N. A. Jeffcoate, [9] D. A. Jones, [29] J. A. Martinez, [29] W. W. Gerrard, [29] J. M. [illegible] rzilay, M. J. Bennett-Jones, [h] C. L. Pratt, G. K. Sconce, E. B. Whittingham, J. P. Woodward. *Part III (O B.):* S. Alstead, R. J. Doyle, R. A. Furniss, J. N. Parrington, Muriel S. Roberts.

N. W. Roberts, J. L. A. Webster, J. Williamson. *Part A (N.R.)*: L. G. Anderson, [6]Marjorie E. Birch, A. Blumfield, C. G. Burgess, [4 7]G. W. Causey, W. N. Chalmers, J. W. Cheetham, [6]D. H. Collins, A. Curtis, P. P. Fox, [7]D. O. Hughes, V. S. Hughes-Davies, A. T. Jones, R. P. Kemp, F. R. Kitchin, E. W. Malcomson, J. L. Mewton, W. J. Poole, M. Solomon, [4 6 7]Honora J. Twomey, [5]T. P. Twomey, [7]R. Wright. *Part I (O.R.)*: E. H. Williams. *Part II (O.R.)*: R. G. Walker, [5]E. H. Williams.

DIPLOMA IN PUBLIC HEALTH.—*Part I:* R. L. Corlett, R. W. Eldridge, A. B. Follows, Susan H. Gilchrist, E. Hulme. *Part II:* Kathleen Edgecombe, R. R. Evans, Bridget M. O. Gordon, F. C. S. Hinsbeck, J. S. Logan, F. L. Smith.

DIPLOMA IN TROPICAL HYGIENE.—G. D. Drury, N. D. Fraser, J. A. L. Innes, C. Ramdeholl.

[6] Distinction in public health.
[7] Distinction in pharmacology and general therapeutics.
[8] First-class honours.
[9] Second-class honours.

and toxicology.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.—
Bessie H. E.
W. W. Fox
Mary I. C. M
G. E. Plowright, Marian M. Reekie, C. F. Stott, Alan Taylor, L. C. Wright. *Forensic Medicine:* E. J. B. Sewell. *(New Regulations—Part I, Forensic Medicine and* *cine):* R. Barnes, A. Bisham, A. N.
Barbara E. Bleasdale, Edith M. Casas
Winifred Dean, J. Dobson, C. G. Eastwood, J. R. P. Edkins, E. G. Elwell, Margaret M. Ferguson, Dorothy A. Geiler, N. Harburn, E. W. Hardman, L. Jones, W. W. Kay, A. L. Kenyon, C. D. Leflaive, J. C. Nicholson, D. Ockman, G. J. Phillips, D. A. Richards, E. Riley, B. Sandler, M. W. Smith, H. W. Thompson, C. Verity, N. S. Walls, G. H. C. Walmsley.

DIPLOMA IN BACTERIOLOGY.—M. M. Barritt, R. Lyth, R. W. H. Miller, Lois Stent, Mary M. Stewart, Emmeline Wade, P. M. Wagle.

DIPLOMA IN PUBLIC HEALTH (*Part I*).—J. R. Beal, C. Campbell, A. H. Heyworth, D. Kemp, A. Meiklejohn, J. S. Sewell, R. Walshaw.

* With second-class honours.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examination indicated:

M.D.—Janet Breakey.
M.B., CH.B. (with second class honours).—F. Ellis, T. H. Pullar.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

AT the later summer commencements of Trinity term, held on July 2nd, the following degrees were conferred:

M.D.—H. G. Holdbrook, R. Schaffer.
M.B., B.CH., AND B.A.O.—W. R. Fearon, H. T. Fleming, M. H. Fridjohn, L. L. Griffiths, L. B. Harris, A. F. Kennedy, R. St. J. Lyburn, Anna M. E. M'Cabe, J. T. M'Ginn, T. B. M'Mahon, E. F. S. Morrison, R. J. Reid, E. B. A. Solomons, C. M. Taylor, R. M. Wilson, J. Beggs *(in absentia)*, N. H. Lindsay *(in absentia)*.
LICENCE IN MEDICINE, SURGERY, AND OBSTETRICS.—R. Kahn.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part I, Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology:* *Elizabeth K. Roberts, *A. H. Thompson, D. B. Bradshaw, I. G. L. Ford, T. A. Bouchier-Hayes, F. P. FitzGerald, D. J. O'Ryan, A. J. O'Connor, H. H. G. Dorman, J. Miller, P. H. Peacock. *In completion:* H. W. Dalton, G. F. West. *Part II, Medicine:* G. R. Beare, J. N. U. Russell, H. T. Fleming, R. T. O'Shea, A. H. O'Malley, L. L. Griffiths, R. St. J. Lyburn, C. M. Taylor, Frances E. Wilson, P. O'Shea, R. I. Reid, G. K. Graham, Anna M. E. M'Cabe, J. F. K. MacCarthy-Morrogh, E. J. M. Bam. *Surgery:* W. R. Fearon, *C. M. Taylor, H. T. Fleming, A. F. Kennedy, E. B. A. Solomons, R. St. J. Lyburn, L. B. Harris, T. B. M'Mahon, L. L. Griffiths, N. H. Lindsay, de, J. T. M'Ginn, F. S. Morrison, tton, W. Caldwell, ons.

D.P *sitology; Physics,* D. H. F. Milmo, *rt II, Sanitation Administration; Vital Statistics;*

*R. A. Q. O'Meara, A. Fava.

DIPLOMA IN GYNAECOLOGY AND OBSTETRICS.—A. El S. A. Ammar, F. El Ahmadi, A. W. Michie.

* Passed on high marks.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION TO THE COUNCIL.

ON July 4th four Fellows were elected into the Council to fill the vacancies caused by the resignation of Sir James Berry and the retirement in rotation of Sir Holburt Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley. The result of the poll was as follows:

	Votes.	Plumpers.
WILLIAM SAMPSON HANDLEY (Middlesex) ...	627	10
CHARLES HERBERT FAGGE (Guy's)	587	14
Sir HOLBURT JACOB WARING (St. Bartholomew's)	560	30
GRAHAM SCALES SIMPSON (Sheffield)	527	48
Charles Coley Choyce	489	12
Thomas Percy Legg	334	14
Robert Milne	364	41

In all 1,091 Fellows voted, including 160 Fellows resident out of *Great Britain and Ireland; in addition 5 votes were found to be* invalid.

Mr. Simpson becomes substitute Member of Council for Sir James Berry until 1931; and Mr. Handley, Mr. Fagge, and Sir Holburt Waring are elected for the full period of eight years.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE following, having passed the Conjoint Final Examination, have been admitted to the Licences in Medicine and Midwifery:

T. G. De V. Coneys, T. J. Gilmartin, W. C. B. Harrison, D. J. Mangan, P. F. Murray, J. F. O'Halloran, M. H. O'Reilly, H. D. Plunkett, M. A. Roddy.

The Services.

PARKES MEMORIAL PRIZE.

THE essay for the next award of the Parkes Memorial Prize will be "The Causes and Means of Prevention of Tonsillitis, with Special Reference to Naval and Military Service." The prize, which consists of 75 guineas and a gold medal, is given every third year for the best essay dealing with hygiene; it is open to certain medical officers of the Royal Navy, Army, and Indian Army of executive rank on full pay.

TESTIMONIAL TO SIR RONALD ROSS.

SECOND LIST OF CONTRIBUTORS.

ON May 11th (p. 879) we published a letter from Sir James Barr and others informing our readers that a fund, called the Ross Award Fund, was being started in order to give some recognition to Sir Ronald Ross for his discoveries on the mode by which malaria is carried, and for his lifelong efforts regarding the prevention of that disease. The letter stated that donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c." The names of those who had contributed to the Fund up to May 17th were printed in our issue of June 8th (p. 1065), the total amount then acknowledged being £2,490. We now print a second list of donors, whose contributions, amounting to £706 18s. 6d., were received between May 18th and May 29th, making a total of £3,196 18s. 6d. on May 29th. The list published below does not include anonymous contributors or contributors whose initials only have been supplied.

Dr. R. Aitken, Dr. R. G. Alford, Miss Anderson, Miss Arbuthnot, Misses M. T. and A. M. Ashburner, Edmund I. Ahns, B. E. Alston, Miss H. J. Aborne.

John Bain, Miss Ellen Baxter, N. E. Ball, F. L. Bradley, Rev. J. T. and Mrs. Barkley, Miss Eliza Broughton, Marion Bruce, Miss Bannister, Mr. and Mrs. W. Blyth, Mrs. M. M. Bevington, Mrs. J. M. Blomfield, Miss Bowie, John Fulton Barr, Mrs. Herbert Brock, Miss A. F. Bladon, Miss Boyd, B. H. Briggs, Lady Grace Baring, Miss L. E. Broadwood, Miss M. Bartleet, J. Stark Browne, Mr. H. Beddington.

Dr. Ernest Carlet, Mrs. Campbell, Mrs. Scott Cooper, The Misses Clark, Dr. Collier, Major Brunel Cohen, Mrs. A. Campbell, Mrs. Crossley, Mr. Edward W. Cox, Miss Ethel Charles, W. P. Connell, R. H. Cotton, J. Campbell, W. F. Carslake, James D. Cowan, W. Roper Caldbeck, Cheviot Rubber, Ltd.

Miss J. Duncan, Miss Mary Duncan, Mrs. Davison, Mrs. Davenport, Mrs. R. Dixon, Dr. M. Dawson, Colonel J. Day, H. M. and W. Drake, G. B. Dibbler, W. S. M. D'Urban, George Drinkwater.

Captain Arthur E. Ewart, Edith N. Evans and H. Winifred Cooke, James H. Edwards, Miss D. H. Fowle, M. A. and A. Eddy and Sister Harriett.

Mrs. A. Flanelle, Miss Franklin, Miss Constance Fenwick, Mrs. Frere, Fred. Fuller, Miss Fovargue and Miss Powell.

Dr. E. W. Goodall, Miss G. E. Gage, Robert M. Galloway, Dr. L. P. and Mrs. Gibson, Miss Gardner and Miss Lawrence, Miss F. Gray, Dr. W. Gosse, Sir Frederick Gardiner, Mrs. S. B. Gotst, P. O. Gordon, Stephen Gillanders, E. M. Gallie.

Dr. C. O. Hawthorne, Miss E. J. Heyworth, James Harper, Dr. Richard Haigston, Mrs. A. M. Holderness, Miss A. E. F. Horniman, J. A. Hutchinson, Mrs. Hurworth, G. C. Hay, L. Harrison, Mrs. Dorcas Hart, Miss A. S. Harrington, W. J. Harding-King, Dr. H. A. Haviland, Miss Dorothy Holman, Miss H. Clements Hassell, J. O. Hackman, O. N. Hollely, A. W. Jones, C. A. Jebens.

F. A. S. King, Alfred Kingdom, Mr. and Mrs. Kreisler.

Professor Luigi Liuggi, C. Lamb, P. Makepeace Lott, Mr. and Mrs. L. C. Lowther, Misses Leslie, Misses Lever, Misses Lewis, Mrs. A. Lane, Mrs. and Mr. J. Lee, R. G. Lawson, H. Lloyd, Lillian M. Leary, Dr. E. le C. Lancaster, Miss Luard, Labu (F.M.S.) Rubber Co., Ltd., Mrs. F. Littington.

Dr. F. G. Mackereth, Dr. E. Marsden, N. Martland, Mary Monkhouse, John Milligan, Mrs. Frank C. Minoprio, Mr. Julian D. Marks, C. Martin, Mrs. A. M. Morris, W. H. Marsh, Miss M. E. Mawson, S. Meakin, R. E. Mainprice, Miss S. Macpherson, Misses Morley, Mrs. Maurice Macmillan, Daniel Murphy, Miss H. M. Mainprice.

William Nuttall, Mrs. Nuttall, Mrs. S. Newman.

Mrs. Oldham.

Sir Horace Pinching, Julian Phillips, Dr. J. Wilson Paton, H. S. Part, A. M. Partridge and Sister, Miss Peck, Miss Pearson, Miss A. Prelyman, Arthur Peto, C. P. Peak.

Mrs. J. J. Richardson, Mrs. Reid, Miss M. Kate Robinson, Thomas O. Ruston, Mrs. Jesse Roberts, R. E. Robins, Dr. F. M. Rowland, H. J. Rudyard, A. Carnegie Ross, Col. A. S. Rooke, L. Ropner, Miss Kate Rogers.

Professor and Mrs. A. W. Stewart, Misses Stirling, R. D. Sisteon, Nurse Stoneham, Margaret Sherwin, Mrs. Stafford, Jesse H. Slatford, Mrs. A. Storey, Emma Smith, Miss Agatha Sadler, Rev. A. Spofford, Mr. and Mrs. Thornton Sharp, R. W. Spranger.

Ernest Taylor, A. J. Tweedie, Dr. H. Twyford, Mrs. Gerald Thompson.

Dr. F. Wyatt-Smith, Miss Watson, Dr. Edward A. Wilson, Mrs. Mary Woodward, Frederick Wagner, B. M. Ward, Albert L. Wright, Mrs. C. T. and Miss D. J. Wilson, Claude F. Westbury, Dr. G. H. Bateson Wright, Charles Wilson, Mrs. E. Walker, Major N. F. Webb, A. Webster, Mrs. Wrench, J. W. Wall.

Obituary.

JOHN MITCHELL BRUCE, C.V.O., M.D., LL.D., F.R.C.P.,

Consulting Physician to Charing Cross Hospital, and the Brompton Hospital.

WE have to record with much regret the death, at the age of 83, of Dr. J. Mitchell Bruce, which took place on July 7th at his house in Harley Street.

Born at Keig, in Aberdeenshire, John Mitchell Bruce received his early education at Aberdeen Grammar School, proceeding thence to the University of Aberdeen, where he took the degree of M.A. in 1856. Following a distinguished career at the Middlesex Hospital he graduated M.B. of the University of London (with honours and the gold medal in forensic medicine) in 1870, and proceeded M.D. in 1872. After graduation he studied for some time at Vienna and other European schools of medicine, and on his return to England engaged in pathological research under Sir John Burdon-Sanderson and Professor Emanuel Klein. In 1871 he was appointed lecturer in physiology and pathology to the Charing Cross Hospital Medical School, becoming assistant physician to the hospital in 1873, and physician in 1882, an appointment he held until his retirement in 1904, when he was elected consulting physician. While on the active staff of the hospital he lectured on materia medica and medicine, and from 1883 to 1890 he served as dean of the medical school; he was also for many years physician to the East London Hospital for Children, to the Brompton Hospital for Consumption and Diseases of the Chest, and to King Edward VII Sanatorium, Midhurst. Elected a Fellow of the Royal College of Physicians of London in 1878, Dr. Mitchell Bruce became senior censor and Lumleian lecturer in 1911, and Harveian orator in 1913. He served also as president of the Medical Society of London and president of the Section of Medicine of the Royal Society of Medicine. For some years he was examiner in medicine to the University of Cambridge, and to the Conjoint Examining Board in England, and examiner in materia medica to the Universities of London and Manchester.

In 1886, when the British Medical Association held its annual meeting at Brighton, Dr. Mitchell Bruce was vice-president of the Section of Pharmacology and Therapeutics, and held the same position in 1895, when the Association met in London. In 1899, at Portsmouth, he was president of the Section of Medicine, having been vice-president at Edinburgh in the previous year, and in 1910 he delivered the address in medicine when the Association again met in London for its annual meeting, taking as his subject "The dominance of etiology in modern medicine." In 1919 he was created C.V.O., and the University of Aberdeen conferred upon him the honorary degree of LL.D. He was also an honorary Fellow of the Royal College of Physicians of Ireland.

Dr. Mitchell Bruce wrote extensively on medical subjects. Early in his career he was on the staff of the *Medical Times and Gazette*, and later co-editor of the *Practitioner*, and assistant editor of *Quain's Dictionary of Medicine*. His publications include *Materia Medica and Therapeutics*, an extremely popular textbook, which first appeared in 1884, and has passed through many editions; *The Principles of Treatment*, which was thrice reprinted; *Lettsomian Lectures on the Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life*; *Lumleian Lectures on Cardio-vascular Degeneration*; and many occasional contributions to our own columns and to those of other medical journals.

Dr. Mitchell Bruce was a man of great academic distinction, an enthusiastic teacher, and a sympathetic and skilled physician, whose habit of mind made him cautious in judgement and earned for him a high reputation as a clinician of the conservative and safe type. He is survived by one son.

Dr. WILLIAM HUNTER writes:

The death of Dr. Mitchell Bruce removes from our midst one who in a rare degree possessed the esteem and affection of the whole profession. By his writings and teaching and outlook on medicine he exercised a profound influence on all those with whom he was brought into contact in the sixty years of his active life. He was a great clinical physician and a great clinical teacher, of whom successive generations of students were proud. As lecturer in physiology, materia medica, and medicine, as dean of the school, and as assistant physician, physician, and consulting physician he rendered memorable services to Charing Cross Hospital and its medical school. His deanship of the school (1883–90) was associated with one of the most formative periods in its history, and by his death it loses one of the most loyal, devoted, and beloved teachers that ever served any institution.

But at this time of loss it is the personality of the man, rather than his services, that are uppermost in the thoughts of those who knew him and enjoyed his friendship—as was my privilege for some forty years. Honoured and honourable, he never lost his interest in all the many developments now connected with the subject of clinical medicine so dear to his heart. He had himself taken a more active part in inaugurating these developments than he ever realized. He formed one of the notable group—made up of Burdon-Sanderson, Lauder Brunton, Ferrier, and Klein—who, in the seventies, laid the basis of that scientific development in the physiological, pharmacological, and histological studies which they were the first to foster. As it happens, it was on these he dwelt in the last conversation I had with him. The occasion was the establishment of the memorial at the Royal Society to the memory of his old friend David Ferrier, and Bruce vividly recalled all the difficulties of that earlier period. Throughout all his life he maintained this same self-sacrificing and modest outlook on the part he himself had played. He possessed a singular geniality and an ever-present courtesy, which endeared him to all; his loss will be felt as a personal one by all who knew him and loved him.

Dr. W. CECIL BOSANQUET writes:

I gladly write a few lines of reminiscence and appreciation of my old chief, John Mitchell Bruce. Coming as a student to Charing Cross Hospital in 1894, I found that Bruce was regarded by all as the most brilliant member of the medical staff, and, having the good fortune to serve under him first as clinical clerk and later as house-physician, I had the best opportunities of realizing the great abilities of this able and accomplished physician. To see him examine a patient in his kindly yet thorough manner was in itself an instructive and impressive training for the beginner, while his explanation of the signs which he elicited was so clear and convincing that the art of medicine, as expounded by him, seemed deceptively easy and straightforward. It was the same with his systematic lectures in the medical school. His clear intellect enabled him to select the essential points in any subject and present them to the student embarking on his clinical work in logical sequence and without confusing detail; while his fluent utterance and graceful style rendered the lectures themselves a pleasure to the hearer. As students, our only complaint was that, owing to his busy practice, Bruce's visits to the hospital were somewhat irregular, and it was not unusual for his class to wait for half an hour in the hall in vain, to hear at last that "Dr. Bruce regrets that he cannot visit this afternoon." When he did come, he came briskly and full of energy. His time was precious; yet he never acted brusquely to his patients or showed less courtesy to a waif in hospital than to a well-to-do patient in his own house. As an adviser in hospital affairs he was practical and sagacious, not a regular attendant at boards and committees, but one whose words were listened to as those of a trusted counsellor. In private life he exhibited a wonderful charm of manner and had always a kindly word for anyone who had worked with him in any capacity. After his retirement from hospital duties he was always a genial member of the social gatherings of their staffs, and will be sadly missed by his remaining colleagues at both Charing Cross and Brompton Hospitals.

Dr. MARCUS CAMPLIN MOXHAM, who died at his home at Aldborough, near Norwich, on June 27th, at the age of 65, received his medical education at St. Bartholomew's Hospital, and qualified L.S.A. in 1886, and M.R.C.S., L.R.C.P.Lond. in 1887. After completing appointments as house-surgeon to the Central London Ophthalmic Hospital, the West Suffolk County Hospital, and the Stroud General Hospital, he engaged in private practice, first at Stickney, Lincs, for twenty-five years, and then at Aldborough from 1919 till the time of his death. In addition he held a post as medical officer to the Aylsham and Erpingham Unions. He had been a member of the British Medical Association for more than forty years. Dr. Moxham was a man of kindly disposition, a good companion, and a conscientious practitioner. He will be greatly missed among a wide circle of friends and patients, by whom he was respected and loved.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week completed the debate on the Address. The House divided for the first time on July 9th, and a Conservative amendment to the Address was defeated by 340 to 220. Later in the week money resolutions were moved, proposing payments to increase the Government's contribution to the unemployment insurance scheme and for other purposes.

On July 9th medical members of Parliament and University members met to form a Parliamentary Medical Committee. Dr. Salter was elected chairman, Dr. Somerville Hastings honorary secretary, and Dr. Morris-Jones honorary treasurer. Thus, to maintain contact with the Government, Ministerialists are selected as chairman and honorary secretary. The honorary treasurer is a Liberal. Dr. Fremantle, the retiring chairman, was elected deputy chairman. The committee now includes eighteen medical members and the University members. It is thus stronger numerically than any previous Parliamentary Medical Committee, and greater activity is predicted for it, with an organized attempt to focus political opinion on health questions.

On July 9th Dr. Fremantle gave a dinner at the House of Commons to fourteen medical parliamentarians, including Lord Moynihan and Dr. Ethel Bentham, the first medical woman to sit in Parliament.

Debate on the Address.

During the debate on the Address in the House of Commons Dr. VERNON DAVIES, speaking on July 5th, suggested that the slum clearances proposed in the King's Speech should be accompanied by improvement of the "slums of the sea." Mr. Arthur Henderson, he said, had declared in a recent article that the accommodation of seamen called for reform, and that a Labour Government was not prepared to take no action. Dr. Vernon Davies suggested that an inter-departmental committee of the Board of Trade and the Ministry of Health should be set up to inquire into the question and to report to the House of Commons. Since the Merchant Shipping Act passed, thirty years ago, the only improvement in the conditions of British seamen had been made in 1906, when the space per man was increased from 72 to 120 cubic feet. The space for lascars was still 72 cubic feet. During the war standard ships were built in which the conditions were greatly improved, but since then there had been a slight setback. Some of our foreign competitors paid more attention to these matters. The Regulations and Instructions for the Survey of Ships, issued by the Board of Trade, made suggestions, and was not compulsory. In Australia and Norway Acts of Parliament made compulsory standards. Australia had medical men whose duty it was to supervise the hygienic accommodation in ships. Great Britain had nothing of the kind, except in the Royal Navy, where, on the staff of the Director-General of Medical Services, was an officer whose duty it was to see that in warships the conditions were hygienic for the men. Surely the same could be done through the Board of Trade in conjunction with the Ministry of Health. At present conditions were chaotic, and shipowners who followed the regulations interpreted them in different ways. One recently inspected vessel had only one wash-house basin, which served for twenty sailors and firemen. Another up-to-date vessel provided the sailors with a messroom in addition to sleeping room, but it was in the forecastle. A vessel with a large crew and a doctor had no hospital. It was not compulsory to provide a hospital in these ships. It was unnecessary to provide sanitary accommodation on a ship unless the owner wished that space to count for reduction of dues for tonnage. Seamen should not now be regarded as men to whom sanitary accommodation and proper hygienic accommodation were of no value.

Small-pox.

In an answer supplied to Mr. Neil Maclean, on July 4th, Mr. GREENWOOD (Minister of Health) stated that 27 cases—not 65 as asserted by Mr. Maclean—in which symptoms suggestive of disease of the central nervous system followed within a month of vaccination were reported to have occurred between July 1st, 1928, and June 30th, 1929. Thirteen were fatal. The report on vaccination, which an expert committee had published last year, was now receiving Mr. Greenwood's careful attention. This committee was still investigating certain questions, and he did not consider a useful purpose would be served by the appointment of a further committee of inquiry.

Replying to Mr. James Gardner, Mr. Greenwood said, on July 4th, that a declaration of conscientious objection to vaccination, made by a mother under the Vaccination Act of 1907, would not exempt the father from liability if he had the legal custody of the child. He could not at present undertake to introduce legislation to place the mother in the same position as the father for the purpose of the Vaccination Acts.

On July 5th Mr. Greenwood told Mr. Groves that 690 cases of small-pox were notified in the county borough of West Ham during the twenty-six weeks ended June 29th, 1929. The disease had generally been of a mild degree. For vaccination of persons resident in that county borough £91 was paid to public vaccinators during the three months ended March 31st.

Mr. Greenwood, on July 8th, told Mr. Groves that since January 1st, 1929, ten certificates had been received in which the words "vaccination," "vaccinia," or "post-vaccinal encephalitis" appeared in the coroner's certificate or the medical certificate of the cause of death. The ages of the deceased persons were respectively: 4 weeks, 4 months, 5 months, 6 months, 8 years, 9 years, 10 years, 17 years, 26 years, and 31 years; inquests were held on the persons aged 8 years, 10 years, 17 years, 26 years, and 31 years respectively. In addition, he had information of seven cases in which death occurred within one month after vaccination. The ages of the deceased persons were respectively: 9 years, 10 years, two of 13 years, and one each of 14, 51, and 58 years.

National Health Insurance.

Mr. GREENWOOD announced, on July 4th, that about 14,800,000 persons in England and Wales were entitled to medical benefit in 1928. Since 1913, when medical benefit came into operation, 46 insurance practitioners had been removed from the medical list.

On July 8th Miss LAWRENCE (Parliamentary Secretary to the Ministry of Health), replying to Dr. Morris-Jones, said she was

aware that a scheme had been submitted by the British Spa Federation to provide hydrotherapeutic treatment for insured persons suffering from chronic rheumatism as an additional benefit under the National Insurance Act. This scheme had received careful consideration, but had not yet been sanctioned. The present list of additional benefits afforded to approved societies a wide variety of remedial treatment from among which they might select those to which to allocate funds available for the purpose out of their disposable surpluses. Before adding further benefits to that list the Minister of Health would require to be satisfied that there was a fairly widespread desire on the part of the societies for such an extension.

Medical Research in India.—On July 8th Mr. BENN (Secretary of State for India) told Major Graham Poole that the report of the Committee on the Organization of Medical Research in India was published about five weeks ago. Some protests were made against the location of the Central Medical Institute at Dehra Dun; but the expenses for the scheme as proposed were approved on January 29th by the Standing Finance Committee of the Legislative Assembly.

Vivisection.—On July 8th Sir ROBERT GOWER asked if the Home Secretary intended to introduce legislation prohibiting the vivisection of dogs. Mr. CLYNES replied that on this subject the Government must be guided by the best possible advice which it could command. Having regard particularly to the carefully considered opinion which was expressed in the memorandum of the Medical Research Council presented to Parliament in 1927, he could not undertake to introduce legislation on the subject.

Dumping of London Refuse.—Mr. GREENWOOD told Sir Alfred Knox, on July 4th, that he was aware of the complaints about the dumping of London refuse at Iver and Little Britain in Middlesex. One district council had adopted special by-laws, and conditions had improved. He had no legal power to deal with particular cases of this kind, but where there was a nuisance or a danger to health the local authority could move. He had power to declare local authorities in default, but that could only be applied on overwhelming proof that a local authority deliberately intended to evade its responsibility. Comprehensive action must await the report from the departmental committee which was considering the general problem of refuse disposal.

Training of Veterinarians in London.—Mr. BUXTON (Minister of Agriculture), replying to Dr. Fremantle on July 8th, said he had not yet received the report of the committee appointed to consider the existing facilities for training veterinarians in London. He understood that the committee was considering a draft report. That report, when received, would be printed and published at an early date.

Colonial Veterinary Services.—Mr. PONSONBY (Under-Secretary for the Dominions) told Dr. Fremantle, on July 8th, that last April a dispatch was addressed to Colonial Governments dealing with the recommendations of Lord Lovat's Committee on the development of veterinary services in the colonial empire, and asking for observations upon them. Replies were being received. In view of the present lack of qualified candidates the Secretary of State was of opinion that the first step towards the further development of the Colonial Veterinary Services should be the institution of the scholarship scheme which the committee recommended. It would not be possible to bring this scheme into operation this year.

Proposed Additional School Dentist for West Ham.—Sir C. TREVELYAN told Mr. W. Thorne, on July 8th, he was aware that the West Ham Education Committee proposed to appoint an additional school dentist. It had not been brought to his notice that an advertisement inviting applications for the appointment at a salary of £450 a year, rising to £500, had been declined by three professional publications on the ground of the salary being below scale. The Board of Education had not prescribed or authorized the salary of this or any other school dentist.

Protection Against Gas Attacks.—On July 9th Mr. MACDONALD told Brigadier-General Clifton Brown that, in view of the recent ratification of the Geneva Gas Protocol of 1925 by most of the important European States, including this country, he did not think this was a moment to press the local authorities to develop plans for the protection of the civil population against gas attack. Much preparatory work had been done by the Committee of Imperial Defence upon this problem prior to the ratification of the protocol, and that work would not be thrown away if, unfortunately, a situation should arise requiring as a measure of prudence the development of plans for this purpose.

Radium.—On July 9th Mr. GREENWOOD told Commander Bellairs that the report of the Radium Subcommittee of the Committee of Civil Research had been brought to the notice of the League of Nations Health Organization. He could add nothing to a reply given on April 18th in regard to international action on the supply and price of radium.

Notes in Brief.

The Colonial Secretary is not satisfied with the information received with regard to the health of the miners in Northern Rhodesia. He has called on the Governor for a further report and recommendations.

The Government proposes to continue and extend the industrial transference scheme, with modifications designed to make it more elastic and more closely adjusted to the circumstances of the various distressed areas.

Model by-laws providing for the use of a mechanical instrument for the slaughter of cattle has now been adopted by over 300 authorities in England and Wales, and the Minister of Health promises to consider legislation making this use compulsory.

Medical News.

IT is proposed to hold an informal luncheon for all Leeds men who are visiting Manchester for the Annual Meeting of the British Medical Association this month. Those who wish to be present at the luncheon are asked to communicate as soon as possible with Dr. J. N. L. Thoseby, 42, East Road, Longsight, Manchester. The time and place will be announced later.

THE annual old students' dinner of St. Bartholomew's Hospital and College will be held in the great hall of the hospital on Tuesday, October 1st, at 7 for 7.30 p.m., with Sir Frederick Andrewes in the chair.

THE annual old students' dinner of St. Thomas's Hospital will be held at St. Thomas's House, Lambeth Palace Road, London, S.E.1, on Friday, October 4th, when Dr. H. G. Turney will be in the chair.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Trocadero Restaurant, on Friday, October 4th, at 7 p.m.

AS already announced the third Victor Horsley Memorial Lecture will be given by Sir Thomas Lewis at University College Hospital Medical School, Gower Street, W.C.1, on Tuesday, July 16th, at 5 p.m., on "Observations relating to the mechanism of Raynaud's disease." The chair will be taken by Sir John Rose Bradford, President of the Royal College of Physicians of London. Admission to the lecture is free on presentation of visiting cards.

AT a meeting of the house committee of the Royal Victoria Infirmary, Newcastle-upon-Tyne, held on July 4th, it was reported that a Rockefeller Travelling Fellowship had been awarded to one of the assistants in the pathological department. The committee expressed its appreciation of the distinction obtained, and noted that this was the third occasion in the last three years on which Rockefeller Fellowships had been awarded to members of the pathological staff of the Infirmary.

THE Fellowship of Medicine announces that it is proposed to hold a week's course in gastro-enterology from July 22nd to 26th at the Prince of Wales's Hospital, Tottenham, in conjunction with the North Middlesex Hospital; post-graduates interested in such a course are asked to communicate as soon as possible with the secretary of the Fellowship. From July 29th to August 24th there will be a course in urology at All Saints' Hospital, Vauxhall Bridge Road, occupying afternoons and evenings. A course in diseases of children will be held at the Queen's Hospital for Children, Bethnal Green, from August 12th to 24th. An intensive course in medicine and surgery at Queen Mary's Hospital, Stratford, from August 26th to September 7th, will consist of lectures, demonstrations, and operative work, occupying the whole of each day. The general course of work, consisting of attendance at the clinical practice of about forty London hospitals, continues throughout the year, and attendance may commence at any time. Details of clinics are provided and the post-graduate is free to arrange his time-table in accordance with his requirements. Copies of syllabuses and all information may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE forty-seventh annual dinner of the West London Medico-Chirurgical Society took place at the Trocadero Restaurant on July 4th, with the president, Dr. Harold Sanguinetti, in the chair. There was a large attendance of members and visitors, and a very agreeable evening was spent. After the loyal toasts had been honoured Mr. Ivor Back deftly proposed the toast of "Success to the West London Medico-Chirurgical Society," and in the course of his speech in reply the chairman gave an account of the society's work during the past year, referring particularly to the conversazione on June 21st, when Professor Claude Regaud delivered the Cavendish Lecture on the treatment of malignant disease by radium, and when the triennial gold medal was presented to Sir Ronald Ross. The health of "The Guests" was proposed by Dr. Julius Burnford, and was responded to by Sir Nigel Playfair and Dr. F. G. Crookshank. Dr. Frederick J. McCann welcomed the representatives of kindred medical societies, on whose behalf Dr. Walter Carr (president of the Medical Society of London) and Dr. Ernest Young replied. The formal proceedings ended with compliments addressed to the chairman by Dr. Arthur Saunders.

THE London County Council is proposing to suggest to the Ministry of Health that a consultative committee should be set up to consider the question of the suitability of films (before they are shown) intended for exhibition to adolescents as a means of instruction in sex hygiene, such committee to be composed of representatives of the Ministry, the Board of Education, and the London County Council in its capacities as public health authority and local education authority.

THE current (June) issue of the *Bulletin of Hygiene* contains a review by Dr. J. D. Rolleston of recent literature on alcoholism, with a bibliography of forty references to journals, theses, or books published in nine different countries.

THE thirteenth international congress of ophthalmology will be held at Amsterdam from September 5th to 13th, under the presidency of Professor van der Hoeve of Leyden. The principal subjects for discussion will be the control of trachoma; the etiology and non-operative treatment of glaucoma; and the diagnosis of suprasellar tumours. We are asked to remind any ophthalmologists who intend to go to Amsterdam for this congress, and who have not yet sent their subscriptions, that it will greatly facilitate the work of the national committee if they will do so at once. Seven hundred members have already been enrolled, and 232 communications, covering all branches of ophthalmology, have been promised. The Transactions will be published, and promise to form a compendium of recent work in this subject. Those unable to go to Holland may, nevertheless, become members of the congress, and so be supplied with a copy of the Transactions, when they appear. Subscriptions, 25 Dutch florins, equivalent to £2 2s., should be sent to Dr. H. M. Roelofsz, Director of the Incassobank, Heerengracht 531, Amsterdam.

ACCORDING to the *Reichsmedizinalkalender* there were 48,507 medical practitioners in Germany in 1928, as compared with 47,338 in 1927. In 1928 there were 3,378 medical women, as compared with 2,078 in 1927. Among the thirteen German cities with more than 400,000 inhabitants, Munich in 1928 had 22.5 doctors for every 10,000 inhabitants, as compared with 7 doctors for every 10,000 inhabitants for Germany as a whole.

THREE fresh cases of leprosy were notified in Germany in 1928; four had emigrated or died during the year, and at the beginning of 1929 there were nine cases in the country.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

HAY FEVER.

DR. J. M. DALZIEL (The Herbarium, Royal Botanic Gardens, Kew) writes: In reply to Dr. J. D. Hindley-Smith's query (June 29th, p. 1189) I would suggest that the dates indicate the "common foxtail grass," *Alopecurus pratensis* L., as the probable source of the exciting pollen.

RETROBULBAR NEURITIS.

IN answer to the inquiry of "Nescio" on July 6th (p. 36), Dr. J. ALDINGTON GIBB (Maidstone) writes: Retrobulbar neuritis is not infrequently originated by disease of the nasal sinuses. In my experience the anterior ethmoid cells have proved to be the most usual cause of this condition. In the recent cases—say, of eight weeks' duration—the improvement following opening and draining of these cells was most dramatic. In a chronic case of over six months' duration, with complete scotoma for colours, and the vision 6/60, the patient's recovery has been complete, the vision returning to 6/12. He has resumed his employment of shunter in a large railway yard.

INCOME TAX.

Cash Basis.

"J. P." is being pressed by the inspector of taxes "to sign a letter promising to pay tax on all the cash that comes in after retirement from the practice." The inspector affirms that other practitioners in the neighbourhood have signed such undertakings, and that the views expressed in this journal, that the assessment of such receipts is not legally justified, is without authority and is incorrect.

*** It is true that there is no specific legal authority for the views in question; that is because the authorities have not taken into court the contention that such receipts were assessable to tax for periods subsequent to retirement. We have no doubt whatever as to the legal position. As we have always said, the cash basis is a mere matter of mutual convenience; the correct basis is assessment on the value of the bookings for the year—that is, the gross amount less a careful and detailed estimate of that portion which is probably irrecoverable. A moment's thought will show that where the volume of bookings is fairly regular year by year, the net value after the allowance mentioned will be approximately the same as the amount of the cash receipts—the latter is more easily and accurately ascertained, and therefore is normally accepted by the authorities. Suppose that when "J. P." retires the inspector seeks to adjust his assessments, what precisely will the adjustment be? (Leaving aside certain technical objections which could be made to that course, he could, no doubt, arrange for the revision of the assessments for six years.) It can only be towards the strict legal basis of bookings. If, for instance, he says, in effect, "This £200 which you received in 1929 after retirement represents bookings of 1927, and that year must be adjusted," "J. P." has the obvious rejoinder, "True, but £210 which I received and returned for assessment as income of 1927 represented work done in 1925, and that £210 must come out when you make the adjustment." The net result of the whole shifting back of the receipts to the years when they were earned would be negligible in the case of a normal practice—if the practice has been growing it would adversely affect "J. P." to some extent, and vice versa if the practice has been diminishing.

LETTERS, NOTES, ETC.

TEAM WORK AT THE BRITISH LEGION VILLAGE.

DR. J. B. MCDOUGALL, medical director, British Legion Village, Preston Hall, Aylesford, writes: In your reviewer's kindly criticism of my book on percussion (July 6th, p. 17) there is an important omission for which your reviewer can scarcely be held responsible. I trust I may be forgiven if I venture to add that the line drawings in the book were executed by one of the settlers in the British Legion Village, an ex-patient in the sanatorium, and that the book itself was printed in the press associated with the settlement for tuberculous ex-servicemen at Preston Hall.

MALARIA TREATMENT OF GENERAL PARALYSIS.

DR. T. GERALD GARRY (Montecatini) writes: With reference to Dr. Dods Brown's remarks on the treatment of general paralysis by malaria infection, reported in the *Journal* of June 22nd (p. 1135), it may interest him to know that it is the custom in Tanganyika (a custom which has possibly existed for centuries) for the native medicine men to send their patients suffering from general paralysis to malaria districts, and from reliable reports the results appear to have been satisfactory.

THE PHOTOSTAT.

IN our report last week (p. 34) of the annual general meeting of the Royal Society of Medicine reference was made to the fact that, in order to make the service of its library better available to Fellows who live at a distance from London, the Society has installed an apparatus known as the "photostat," for making rapid photographic copies from the pages of books and journals. This is offered as an alternative to the old method, involving the laborious copying of abstracts, which even then failed to reproduce the illustrations. The photostat is an apparatus of rather surprising bulk and complexity, and occupies a large room at the Society's house. The process, however, is simple, the printed page being placed in position, illuminated by mercury vapour lamps, and the exposure made direct on to sensitized paper (with a prismatic reversing arrangement, so that the print comes the right way round in the reproduction), which is immediately developed and made ready to send to the inquirer. This innovation should be appreciated by Fellows of the Society in the provinces and abroad.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 23.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

21. The Leprosy Reaction.

R. GREEN (*Trans. Roy. Soc. Trop. Med. and Hygiene*, January, 1929, p. 367) regards the "leprous reaction" sometimes occurring among lepers as a condition to which more attention should be paid, in view of its being a distinct and important clinical entity. The reaction may be mild, resulting in subsequent amelioration of the disease, or severe, with distressing symptoms and scarring, or, in some cases, death. Depending upon its occurrence in relation to the stage of the leprosy, especially Muir's second stage, the reaction seems to lead to rapid progress of the disease; it may be regarded as an acute exacerbation and a defence reaction against the invading *Mycobacterium leprae*. Green, working at the Federal Leper Settlement at Kuala Lumpur, adopted as the standard treatment of the condition injections of 10 minims of 1 in 1,000 adrenaline solution in 20 minims of normal saline twice a day for a week or ten days, thereby relieving the essential nerve pains and apparently shortening the reaction period. Notes of cases treated orally with ephedrine hydrochloride are given in which benefit resulted both to the skin lesions and the nerve pains. The reactions are characterized by swelling and erythema of existing lesions, with reappearance of fresh rose-coloured and often painful nodules. Fever is not always present, but there is marked acceleration of blood sedimentation rate, apparent granulation of lepra bacilli in the lesions, and a definite increase in the serum globulin. The newly formed cutaneous lesions may be classified into three types: (1) rapidly occurring superficial lesions with bleb formation becoming infected and leading to scarring and disfigurement; (2) a slower and more usual type without tendency to bleb formation; and (3) a less common type in which deeply situated painful subcutaneous nodules rapidly form without tending to break down and gradually becoming absorbed.

22. The Fate of Untreated Cases of Syphilis.

H. SÆTHRE (*Derm. Woch.* April 13th, 1929, p. 554) has collected statistics in an attempt to determine the question of the alleged increase in the number of cases of aortitis, tabes, and general paralysis, and formulates the following conclusions. In 2,181 cases of primary and secondary syphilis no specific treatment was given during the period 1891–1910; some of these patients had recent complications, and in 1925 there were 471 cases under observation. Recent nervous complications occurred in 3.4 per cent. (no examination of cerebro-spinal fluid). Almost all of the 2,181 patients had extensive exanthemata; many had alopecia and leucoderma, and not infrequently cases of iritis were observed also. Ten to forty years after infection 40 per cent. of the 228 cases under observation were without symptoms; of these, 10 per cent. had a positive Wassermann blood reaction. Syphilis of the central nervous system appearing many years after infection was remarkably rare; tabes was only noted in 1.28 per cent. and neuro-syphilis in 2.34 per cent. of 471 cases. In the whole series of 2,181 patients only 13 cases of general paralysis were observed—approximately 0.6 per cent., having regard to possible sources of error. The diagnosed recent complications in the central nervous system did not indicate any tendency to the later occurrence of tabes and general paralysis. All the patients with tabes and general paralysis had in the early stages extensive exanthemata. Only 65 cases of aortitis and other vascular lesions were present among 371 living or dead patients ten to forty years after infection (17.5 per cent.). The author adds that his Norwegian statistics differ widely from recent German figures quoted by him; these German figures indicate incidence of aortitis in 1906–7 as 33 per cent., in 1915 as 63 per cent., in 1924 as 74 per cent., and in 1925 as 83 per cent., although the percentage of cases of visceral syphilis was not increased.

23. House Mice as Carriers of Infection.

E. PALIER (*Bull. de l'Acad. de Méd.*, May 7th, 1929, p. 587) points out that the pneumococcus of Fränkel, the causative agent of fibrinous pneumonia, is present in the mouths of the majority of healthy persons, but with very attenuated virulence. Cold cannot be so great a factor in causing pneumonia as is supposed, since cases are almost unknown in Arctic regions. Yet the disease is more prevalent in the winter, and Palier remarks that this is the season when houses are particularly infested with mice. Rats are immune to the pneumococcus, but become susceptible to it after its passage through mice. Palier concludes that the mouse is the chief, if not the sole, agent in the transmission of pneumococcal diseases. Support is given to this view by the work of Mauriac, who showed that mice can become infected with pneumococci; that infection can be carried to other mice and to human beings by fleas; and that, therefore, this parasite can play a part in the transmission of the disease. Colon bacilli and other intestinal microbes have also been found in the cadavers of mice and rats, and it is possible that diseases such as appendicitis may be caused through the agency of these animals. As prophylactic measures, Palier advocates the avoidance of indiscriminate expectoration; the construction of houses of a kind unfavourable to infestation by mice and rats; greater care as regards the preservation of food from contamination by these rodents; and, whenever possible, their extermination and incineration. He adds that Béguins has shown that cats do not transmit pneumonia to any considerable extent.

24. The Prognosis of Pachypleuritis following Artificial Pneumothorax.

C. ROUBIER (*Journ. de Méd. de Lyon*, April 5th, 1929, p. 223) has found that among tuberculous patients who have undergone artificial pneumothorax a hyperplasic pachypleuritis follows a pleuritic effusion and terminates in complete adhesion of the parietal and visceral pleura. This condition exhibits three clinical stages. (1) A stage of effusion is characterized by all the signs of more or less extensive effusion. This may often fill the pleural cavity completely, substituting a hydrothorax for the artificial pneumothorax. In spite of its volume this effusion often causes but little [illegible] pachypleuritis follows; [illegible] re somewhat modified; [illegible] thickening and induration, and it is often difficult to find the pleural cavity. This fibrous pachypleuritis occasionally undergoes calcification; puncture then becomes impossible, and further insufflations cannot be performed. (3) The next stage is one of established adhesion, in which the thoracic retraction, which commenced in the preceding stage, increases more and more, completely immobilizing the affected half of the chest. Roubier thinks that the prognosis in these cases is far from being as grave as might be expected. In many cases the fibrosis appears to exert a favourable influence on the progress of the disease. Generally speaking, the prognosis is better when the adhesive fibrosis occurs later and more slowly, but this rule is far from being absolute; if the early, rapidly progressive adhesion indicates generally a grave prognosis; the author has seen cases in which this has been followed by considerable improvement generally and locally, suggestive of actual cure. It is nevertheless certain that, in general, the prognosis will be better if the adhesion occurs at a later period, when the lung, having been compressed for a long period, has undergone sclerosis and an actual artificial fibrothorax has been established.

25. The Distal Phenomena of Hyperpiesia.

C. F. COOMBS (*Bristol Med.-Chir. Journ.*, Spring, 1929, p. 35) calls attention to the diversity of the cerebral symptoms that may accompany high arterial tension, and discusses the parallelism between these phenomena and those seen in other organs. For example, the distal effects of high pressure in relation to the muscular functions of the cardiac wall and the leg are analogous, and it is clear that in hyperpiesia two kinds of interference with muscular function occur: a transient attack, in which pain is the prominent symptom; and a more lasting condition, which involves permanent injury of the parts affected. In the case of the heart a third group must be added—namely, the slowly progressive degradation of muscle function. The objective cerebral phenomena of high blood pressure show the same three groups. Cases are cited illustrating these points, and the author has little doubt that these phenomena, whether gradual or abrupt in onset, temporary or permanent in their results, are intimately related to the high arterial tension. However, it seems that the relation is not direct but is mediated by arterial degeneration, and that it is not the high pressure so much as the arterial wear and tear which the pressure has exacted that is responsible for these distal manifestations. Those phenomena usually ascribed to arterial spasm and obstruction are discussed, and it is shown that these are really due to a failure of arterial function; in illustration of this the pathology of ischaemia cordis (the

angina of effort) is reviewed. From the evidence adduced Coombs concludes that all the distal phenomena of high arterial tension can be ascribed in part to a gradual wearing down of the elasticity of the arterial tree—that is, to progressive arterial failure.

26. The Nervous System in Typhus.

P. DECOURT (*Paris Méd.*, April 27th, 1929, p. 400) states that nervous manifestations may occur during active typhus or in convalescence several days after the temperature has fallen. In the course of the disease, in addition to headache, insomnia, and delirium, diplopia is one of the earliest symptoms, appearing sometimes on the first day of disease or frequently at the same time as deafness. Myoclonus, chiefly involving the upper limbs and the muscles of the trunk and face, is a frequent occurrence, and is often transient. Attacks of hiccup may occur and may be regarded as a form of myoclonus. Contractures may affect any part of the body, but chiefly the limbs. As a rule they are ill marked, but sometimes they become intense without being accompanied by any disturbance of the reflexes. Tremors of various types are also fairly frequent and chiefly affect the limbs, predominating in the extremities. The eyes may or may not react to light; spontaneous nystagmus is frequent. A few days after the temperature has fallen contractures may develop; tremors of the Parkinsonian type, accompanied by hiccup, myoclonus, and jerky movements resembling chorea, paraesthesiae, cramp, and especially asthenia, may be remote sequels of typhus.

27. Inflammation of the Tendo Achillis in Influenza.

H. DEUTSCH (*Med. Klinik*, May 3rd, 1929, p. 710) during the last two years has seen some ten cases of inflammation of the tendo Achillis following influenza. As the patients had almost always been confined to bed, a traumatic origin, which is the usual cause of this condition, could be excluded. In most cases the affection was bilateral, although one side was usually affected one or two days later than the other. It usually developed a few days after the temperature had become normal. The whole tendon became thickened and painful, and the overlying skin was sometimes reddened. The inflammation subsided in ten to fourteen days, but tender nodules might persist for months. The temperature was only raised in those cases in which the influenza had not yet subsided, and as a rule the temperature was subfebrile. Treatment consisted in rest in bed and warm damp compresses. Deutsch adds that the complication does not appear to have been previously described.

Surgery.

28. Epithelioma of the Penis.

A. J. DEAN, jun. (*Arch. of Surg.*, April, 1929, p. 1273), records a clinical study of 75 cases of epithelioma of the penis. He defines the principal factor in the causation of penile cancer as a tight prepuce which is generally difficult to retract, retained secretions being a source of chronic irritation and hard inspissated smegma a factor of mechanical irritation; fatty acids may cause chemical irritation. Phimosis alone occurred in 74 per cent., and syphilis combined with a degree of phimosis in 20 per cent.; in 3 per cent. leucoplakia preceded the cancer. The most common site for the first symptom to appear was on the glans, in the form of a small sore which gradually increased in size until pain developed; there was generally a purulent discharge from under an inflamed prepuce. There are two clinical varieties of penile epithelioma, the papillary and the flat. The former consists of a densely matted villous overgrowth with a broad base covered with areas of slough on the surface and cauliflower-like in appearance. The flat carcinoma is usually an indurated area with an ulcer of irregular outline in the centre which is covered with a foul greyish or greenish-yellow slough. Both types of lesion are squamous carcinomas, which spread by progressive involvement of contiguous structures; metastases occur by embolism later in the course of the disease, and are encouraged by any treatment which incompletely destroys the primary lesion. Treatment depends on the size of the primary tumour and how deeply it has penetrated; if the primary lesion is 2 cm. or less in diameter and is superficial, without metastases, it can be treated with a radium plaque, the dose being 1,200 millicurie hours per square centimetre, at 1 cm. distance. Of cases treated in this way 92 per cent. were successful. For primary tumours larger than 2 cm. in diameter, irradiation, followed in three to four weeks by conservative amputation, is the treatment employed, and this was successful in 61 per cent. of cases. Where patients are not seen until both the primary lesion and metastases exist, amputation of the penis was performed with a radical dissection of the groins. Operative treatment was preceded by irradiation, but neither was satisfactory as the disease was seldom eradicated, and infection of the wound was frequent. A more recent method of treatment of advanced cases has been the amputation of the penis under spinal anaesthesia with a preliminary injection of ephedrine, precautions being taken to ensure prompt healing by primary union. This operation gives little shock, and by removing the source of infection lymphatic absorption ceases and inflammation in the regional nodes subsides. The health of the patient can then be built up and irradiation will be more effective; the dissection of the groins can be performed at a later date when no time will be lost in amputating the penis and the danger of post-operative suppuration is diminished.

29. Surgical Treatment of Raynaud's Disease.

A. W. ADSON and G. E. BROWN (*Surg., Gynecol. and Obstet.*, May, 1929, p. 577) discuss the treatment of Raynaud's disease by resection of the upper thoracic and lumbar sympathetic ganglia and trunks, thereby blocking the vasomotor paths to the parts affected. Notes of five cases are given in which marked and maintained vaso-dilatation in the feet followed the lumbar operation; similar successful results followed intrathoracic ganglionectomy by the dorsal approach in two cases in which the hands were affected. In two cases, however, cervical sympathetic ganglionectomy was unsuccessful in producing vaso-dilatation or in relieving the symptoms. From an anatomical and physiological consideration of the innervation of the arteries of the upper and lower extremities with the view of interrupting the efferent vaso-constrictor impulses, care must be taken that the section in the lumbar area is high enough, and that that in the thorax is low enough. Since the distribution of rami is not constant, and in order to avoid the possibility of missing fibres, resection of the lumbar sympathetic trunk is advised, including the ganglia *in toto* from above the second lumbar to a point below the fourth ganglion. In the cervico-thoracic area it is important to include the second thoracic ganglion, and make a thorough resection of the second thoracic and the cervico-thoracic ganglia with the intervening trunk, in order to interrupt all vaso-constrictor impulses passing directly to the first and second thoracic spinal nerves and arteries, as well as to sever the efferent fibres passing through the ganglia and trunk to the cervical ganglia and thence to the brachial plexus. In the author's first case two (bilateral) operations were performed—namely, resection of the second thoracic ganglion, the cervico-thoracic ganglion, and the intervening sympathetic trunk on the right side, followed later by a similar resection on the left side. The steps of the cervical and lumbar operations are described in detail. The authors conclude that the therapeutic effects of lumbar and dorsal sympathetic ganglionectomy have been so striking and lasting in their experience as to warrant the belief that Raynaud's disease can be surgically controlled by these methods.

30. Results of Operations for Hallux Valgus.

A. BERNTSEN (*Ugeskrift for Laeger*, May 9th, 1929, p. 397) reviews the results of the operations performed for hallux valgus at his hospital. Of 49 patients, as many as 45 were women. After an interval of one to eight years since the operation the results were checked in every case, in 35 cases by a medical examination, and in 14 cases by answers to a questionary. Altogether ninety toes were operated on, the operations being performed on both sides in the overwhelming majority of the cases. Three kinds of operation were performed, but common to all three were resection of the head of the first metatarsal bone, the removal of the sesamoid bones, and the displacement of the pull of the extensor tendons in the median direction. The sesamoid bones were removed for fear of the formation of troublesome adhesions, but the author admits that Saudelin's statistics show that good results can be achieved without this measure. After the operation a pad of gauze was fixed between the first and second toes, and the foot was secured in plaster-of-Paris up to the ankle, and in such a way as to maintain the foot well arched. The plaster and stitches were removed after fourteen days, and after one more week in bed the patient was allowed to get up, being provided with supports modelled on a plaster cast. The subsequent examination showed that subjective improvement had been achieved in 73 of the 90 cases, and objective improvement also in 73 cases, no recurrence of the deformity being demonstrable. The cases of subjective and objective improvement were usually identical, but there were a few cases in which the improvement was only subjective or objective. The patient's age did not appreciably influence the results, as many as seven of the patients showing subjective improvement being over 50 at the time of the operation. The failures (seventeen toes belonging to nine patients) could not be explained as the result of the patient neglecting

to use any special support after the operation; but it was significant that among the failures were four toes accompanied by pes cavus, and seven which were the seat of arthritis deformans. These two conditions should therefore be regarded as contraindications to any operation for hallux valgus.

31. Injection Treatment of Spontaneous Thrombosis.

SCHAEFER (*Med. Klinik*, May 3rd, 1929, p. 708) suggests that in cases of spontaneous thrombophlebitis of the superficial vessels the veins affected should be blocked by injecting one of the solutions commonly used in recent times for the obliteration of varicose veins, thus producing an artificial thrombus proximal to the original lesion. By this means the dissemination of emboli from the spontaneous thrombus, which in its early stages is not very firmly adherent to the vessel wall, is prevented; the artificial thrombus is at all stages so firmly adherent that embolism never occurs, and the need is avoided for prolonged rest, so irksome to a patient with practically no symptoms. He has used injections in three such cases with entirely successful results, keeping the patient recumbent for one day only after the injection. He suggests that a similar method, after suitable preliminary experiments, might possibly be applied to the treatment of thrombosis of deep veins—as, for example, injection at the saphenous opening where the long saphenous vein joins the femoral.

32. Acute Cystitis as a Complication of Influenza.

J. A. WEIJTLANDT (*Nederl. Tijdschr. v. Geneesk.*, May 11th, 1929, p. 2262) records five illustrative cases of cystitis in influenza patients aged from 17 to 37. While as a rule cystitis is more frequent in women than in men, four of the patients were males and only one a female. The usual symptoms of cystitis—namely, frequent micturition, pain, and pyuria—were present. In two instances there was macroscopically evident haematuria, and in all blood was found on microscopical examination, with an excess of leucocytes. At the height of the attack albumin was also found in the urine. In two cases frequency of micturition was not increased even in the acute stage, although the pain was severe. On cystoscopic examination, which was undertaken in three cases, the vesical mucosa showed a diffuse redness and oedema. The renal function as determined by the indigo-carmine test was unaffected in these cases. Two cases were complicated by pyelitis and epididymitis respectively in convalescence. No regular bacteriological examination was carried out, and on two occasions no special treatment was required. Comparatively little has been published on the urological complications of influenza in the last fifteen years. Goldberg recorded four cases of metastatic influenzal prostatitis in 1920, and cases of urethritis and epididymitis in 1921, while Smirnov in 1926 recorded cases of paranephritis, renal carbuncle, pyelonephritis, and pyelitis. In view of the fact that Weijtlandt saw his five cases in the course of six weeks he maintains that acute cystitis has been much more frequent during the last influenza epidemic than previously.

33. Essential Thrombopenia.

F. VAN GOIDSENHOVEN (*Rev. Belge des Sci. Méd.*, February, 1929, p. 97) publishes thirteen cases of essential thrombopenia treated by ligature of the splenic artery. After this operation slow atrophy of the spleen sets in, with functional modifications similar to those which follow splenectomy. The mucous and cutaneous haemorrhages quickly cease, and the number of blood platelets increases and reaches the normal. The contractility of the clot is usually greater, the bleeding time is improved, and the ligature test is favourably modified. The immediate danger of the operation is only slight, but usually it is advisable to transfuse as well. As compared with splenectomy, the results, although slower in appearing, are equally good, and the operative risks are less. The author adds that the operation is especially advisable in acute cases, or in chronic cases where the general state is bad.

34. Carcinoma Arising in a Tuberculous Fistula.

W. KREY (*Deut. Zeit. f. Chirurg.*, April, 1929, p. 355) gives details of the clinical history and treatment of a case of squamous-celled carcinoma associated with long-standing suppurating fistula from the knee-joint connected with old tuberculosis of the femur. The malignant growth was restricted to the orifice of the fistula and did not extend along its track. The author regards this as a special type of carcinoma—a fistula carcinoma arising from the irritation caused by the chronic discharge from the fistula, and allied to the malignant diseases of the skin following the irritation of tar, soot, and *x* rays. The limb was amputated and the patient has developed no recurrence after two years. The histology of the growth is discussed and illustrated, and the author includes a useful review of the literature bearing on this rare form of malignant growth.

35. Alcohol Injections in Trophic Ulcers.

A POSSIBLE therapeutical improvement on Leriche's operation of decortication of the arterial wall in order to improve the blood supply to a limb is advanced by C. F. MCCLINTIC (*Journ. Amer. Med. Assoc.*, March 23rd, 1929, p. 956). He exposes the femoral artery in the lower two-thirds of Scarpa's triangle and injects 1 to 2 c.cm. of 95 per cent. alcohol with a very fine needle into the nerve-bearing tissue of the artery wall. When completed there is a collar of alcoholized tissue completely surrounding the artery. The effect is said to be immediate; the limb becomes flushed, its temperature is raised, and there is no period of vaso-constriction. Shock is very slight, and there is little risk of damaging the artery. McClintic states that the results have proved to be more lasting than periarterial sympathectomy, as advocated by Leriche. The four cases reported are an indolent ulcer, an ulcer from senile arterio-sclerosis, a varicose ulcer, and a chronic traumatic ulcer. These four patients had negative Wassermann reactions, no sugar in the urine, and normal blood sugar figures. All the ulcers healed healthily within two weeks of the operation, and six months later the flesh was healthy. The conditions for which McClintic suggests this operation, in addition to those reported, are Raynaud's disease, chronic arthritis deformans, painful acroparaesthesia, gangrene from frost-bite, *x*-ray burns, certain types of hypertension, and as a preliminary to amputation for gangrene.

Therapeutics.

36. Modern Remedies for Asthma.

P. VALLERY-RADOT and F. CLAUDE (*Arch. Méd. Chir. de l'Appareil Respirat.*, December, 1928, p. 459) discuss critically the newer methods of treating asthma, and commend ephedrine, *x* rays, certain forms of sensitization, and bleeding. They remark that ephedrine is of especial value in cases of nocturnal asthma, or when the attacks occur at more or less regular times. Nocturnal asthma can often be prevented by the administration of 25 to 50 mg. of ephedrine (Merck) when going to bed, and diurnal attacks by similar treatment one or two hours before they are expected. Ephedrine is much less effective when given during an attack, and the authors obtained only 56 per cent. of good results. It has to be given in the first few minutes of an attack, otherwise it is of little use. They consider this the best form of treatment of the milder varieties of asthma, but do not advise it when the attacks are severe. Ephedrine has also proved useful when given by the mouth; the total dose in twenty-four hours must not exceed 150 mg. With regard to sensitization methods, the authors have used intradermal injections of Witte's peptone for four years, and commend this in cases where there are no signs of any irritative condition of the bronchi or lungs. They use a 50 per cent. solution of peptone in distilled water. The intradermal injections are given in the deltoid region, care being taken that the fluid enters the skin itself and does not pass beneath it. A white prominence forms and increases rapidly in size, like an urticarial spot; this disappears almost entirely in about twenty-four hours. The first injection given is 0.1 c.cm. of the solution; if the reaction is not too intense twice this dose is given on the following day, and 0.3 c.cm. on the third day, this being the maximum dose advised. The authors report very satisfactory results in many cases, but not in all, and emphasize the point that the size of the dose must be graded to suit individual patients. Treatment by *x* rays is advised for those cases which are unsuitable for ephedrine or peptone treatment; the *x* rays act by originating protein shock. Heliotherapy is said to be preferable in the case of children. Bleeding has also been found effective in some cases, and the authors think that this method might be tried more frequently, since it often terminates a crisis quickly.

37. Cod-liver Oil in Tuberculosis.

G. R. BOYES and J. S. WHITE (*Brit. Journ. Tuberc.*, April, 1929, p. 75) discuss the value of cod-liver oil in the treatment of tuberculosis and review the literature on this subject, with especial reference to the parts played by its content of vitamins A and D. They agree that in order to obtain the maximum effect from it as regards the promotion of calcification in tuberculosis it is very necessary to provide an adequate amount of calcium salts, either by regulating the diet accordingly or by administering suitable calcium preparations. In the preparation of the oil it is essential to estimate separately the amounts present of the two vitamin factors, since the curative effects of one do not influence the lesions resulting from the deficiency of the other. There is, moreover, no parallel between the relative amounts of each present in different samples. They quote Kerschner, who, in 1926,

pointed out that by increasing the calcium content of the body in tuberculosis the demineralization caused by the disease is overcome and the normal calcium balance restored, a condition very essential to health. Moreover, the deposition of calcium in tuberculous foci promoted healing by inducing fibrosis and subsequent calcification; phagocytosis is also favoured by calcium administration. The authors refer to Green and Mellanby's article in the *British Medical Journal* (1928, vol. ii, p. 691) with reference to the significant part played by vitamin A in raising the body resistance to infection, and comment on the necessity of extracting the oil from the cod's liver with as little delay as possible, and under conditions which reduce to a minimum the detrimental effects of atmospheric oxidation, which is known to destroy this vitamin.

38. Sodium Thiosulphate in Mercury Poisoning.

T. E. MCMURRAY and G. G. GIBSON (*Med. Journ. and Record*, May 1st, 1929, p. 519) record five cases of mercury poisoning, not to prove that sodium thiosulphate is the only important antidote for this condition, but to show that, owing to its low toxicity, it may be advantageously used with other routine measures. One patient had taken three mercury bichloride tablets, another had swallowed four, two had each taken two tablets, and the last patient only half a tablet. The cardinal symptoms of mercury poisoning were present in all these cases. The administration of sodium thiosulphate gave much relief within a few hours, and all the patients recovered. The treatment employed was gastric lavage with white of egg and sodium bicarbonate solution, followed by 10 per cent. solution of sodium thiosulphate, some of which was left in the stomach. One ounce of the 10 per cent. solution of the drug was given intravenously three times a day for two days, and 2 oz. by the mouth every two hours for the first day, then three times a day for four days. In one case a high enema of 300 c.cm. was given on two successive days, and in another case two high enemas, each of a pint. Supportive treatment was instituted and catheterization performed when necessary. The authors state that bowel and kidney lesions clear up more rapidly under the sodium thiosulphate treatment, and that very large doses of this salt can be used with impunity, and seem to have more effect than smaller ones.

39. Specific Treatment of Chancroids.

H. J. GORDON (*Urol. and Cut. Review*, April, 1929, p. 233), from a comparative study of 221 cases of chancroids, two-thirds of which were treated by old standard methods and the remainder by Rosenwald's method, came to the conclusion that the latter effected a saving of 50 per cent. of the days necessary to effect a cure in each case. The procedure is as follows. After gently cleaning the chancroidal ulcer a thin piece of cotton-wool, well moistened with Rosenwald's suspension (calomel 1 oz., zinc sulphate 2 oz., camphorated tincture of opium 2 oz., lime water 8 oz.), is applied to the ulcer for one day by the use of a condom. At the end of twenty-four hours the dressing is removed and replaced by Rosenwald's ointment (zinc oxide, starch, boric acid, green camphor, 1 oz. of each, 3 per cent. carbolated vaseline 12 oz.) applied on cotton-wool. In a day or two the diseased tissue separates, usually *en masse*, leaving a clean surface which rapidly heals. Owing to the early sterilization of the ulcer buboes do not develop. The treatment has little or no effect upon chancres, and breaking down of the lesions after healing is, in Gordon's experience, pathognomonic of syphilis.

40. Local Application of Besredka's Antivirus.

G. DENES (*Studium*, April 20th, 1929, p. 152) reports good results from the treatment of vaginal discharge by means of tampons soaked in a filtrate of broth culture prepared from the specific organisms concerned. In over sixty cases where this treatment was applied the discharge was cured and remained cured. Denes adds that this treatment can be used in many cases where local applications are indicated, and instances otitis, furunculosis, erysipelas, and blepharitis. He states that no general reaction follows, and that the procedure is simpler than injections. For some obscure reason the results appeared to be better in chronic or subacute morbid processes.

41. Action of Adrenaline after Sympathectomy.

P. TOMESCO (*Bull. et Mém. Soc. Méd. des Hôp. de Bucarest*, February, 1929, p. 48) describes the effect of intravenous injections of adrenaline on patients who had undergone section of the cervical sympathetic. Four epileptics were chosen, and for the purpose of comparison a normal individual whose response to atropine, according to the method of Danielopolu, gave the same vegetative formula as the sympathectomized patients—namely, hypo-amphotonic. An intravenous injection of 1 c.cm. of a 1 in 100,000 solution of adrenaline was given, and plethysmographic tracings were taken. Care was exercised to make the results comparable in every way, and the experiments were repeated on several occasions. The tracings showed that peripheral vaso-dilatation was in every case more feeble in the sympathectomized patients, and that the length of this phase was shorter than in the normal. In the control case it lasted from 111 to 115 seconds, while in the sympathectomized it lasted only 64 to 99 seconds.

Anaesthetics.

42. Anaesthesia for Head Operations.

L. A. RETHWILM (*Anesth. and Analges.*, March-April, 1929, p. 120), from an experience of 4,238 anaesthesias during a period of over three years, reviews the various anaesthetic procedures and preferences in operations about the head, excluding brain surgery. Nearly 3,000 tonsillectomies alone were performed under general anaesthesia induced with the nitrous oxide-oxygen-ether sequence, followed by ether-oxygen vapour given through a mouth-hook at the side of the cheek. Two bottles of ether were used in sequence, so that a stronger vapour could be obtained as desired. Light anaesthesia, with the reflexes not completely abolished, was aimed at in order to prevent aspiration, and it was found that recovery was quicker and better than with deep anaesthesia. In eye work a similar technique was adopted, but in 55 cases nitrous oxide-oxygen anaesthesia was used because of some such condition as diabetes, or because it was desired that the return to consciousness should be smooth, with a minimum of straining, movement, or vomiting. For radical intranasal sinus operations the same technique was employed, though the patient was kept more deeply under with a post-nasal plug to shut off blood and secretions from the pharynx; for intranasal antrum operations and mastoid work this form of anaesthesia was found to be very satisfactory. Ether-oxygen vapour was given for oesophagoscopies, laryngoscopies, and bronchoscopies, with the patient deeply under to enable the instruments to be inserted quickly. From this series of cases Rethwilm concludes that all patients requiring head operations can be satisfactorily anaesthetized with ether or nitrous oxide-oxygen, or a combination of the two, according to the suitability for each individual case. The second is considered the best anaesthetic for eye and mastoid operations, dental work, and tumours about the head and neck; it can be administered intrapharyngeally when the cautery has to be used, or when breathing is mechanically obstructed.

43. Anaesthesia produced by Barbituric Acid Compounds.

H. STEINER (*Narkose und Anaesthesie*, April 15th, 1929, p. 103) records his observations on 170 cases in the obstetrical and gynaecological department of the Cantonal hospital at Aarau in which numal, or allylisopropylbarbituric acid, was employed as a general anaesthetic. It had the advantage of rendering unnecessary the injection of morphine and atropine before the operation. As regards the dosage, 1 cg. of numal was usually given per kilo of body weight; since the solution used contained 10 cg. per c.cm., a patient weighing 50 kilos would require 5 c.cm. The drug is given intravenously, and the administration should be carried out very slowly. It is important that the anaesthesia should be induced in a quiet room. This anaesthetic is said to be specially suited for cases in which it is desirable to reduce ether and chloroform to a minimum. Small doses of pantopon are very effective in controlling the stage of excitement which may occur after its administration. A previous reference to this form of anaesthetic was published in the *Epitome* on May 25th (para. 503).

44. Rectal Anaesthesia with Ether Oil.

F. LEMPERG (*Deut. Zeit. f. Chir.*, April, 1929, p. 43) records his observations on 100 cases in which anaesthesia was induced by rectal injections of ether oil. The composition of the mixture used was: ether 100 parts, olive oil 45, cacao butter 50, liquid paraffin 45, alcohol 8, quinine hydrochloride 1. The volume of the mixture is 260 c.cm., and 2 grams of ether are given per kilo of body weight. The chief advantages of the method are detailed as follows. It renders the presence of an anaesthetist unnecessary in operations on the face and middle ear. The anaesthesia can be entrusted to students or experienced nurses. Costly anaesthetic apparatus is unnecessary. The long duration of the anaesthesia (three to four hours) is a useful feature. The main drawback of the method is that an operation must not be undertaken until an hour after the injection, so that the method is unsuitable for urgent cases.

Obstetrics and Gynaecology.

45. Pregnancy complicated by Concurrent Appendicitis and Pyelitis.

E. LIEK (*Zentralbl. f. Chir.*, April 13th, 1929 p. 907) has performed approximately 1,500 appendicectomies, 200 of which were for chronic recurrent appendicitis, yet he has found occasional difficulty in the differential diagnosis of appendicitis and pyelitis occurring in pregnancy. He describes the case of a woman, aged 29, who was seven months pregnant. After an indigestible meal she had pain in the right flank, without vomiting. The temperature was normal, the pulse 80 to 84, and nothing was found on vaginal examination. The skin was very tender from the right groin upwards to the kidney region. The patient had had pyelitis in the third month of pregnancy; on this occasion a catheter specimen was turbid and contained a large number of leucocytes and *B. coli*. Liek's diagnosis was pyelitis of the right kidney with a possibility of concurrent appendicitis. The next day spontaneous abortion occurred, the child dying in half an hour. On the third day pain and slight fever were present, without other symptoms. Two days later the temperature rose suddenly to 101.5° F. and the pulse to 130. Profuse bilious vomiting occurred, and the abdomen was tense and very tender, giving a typical picture of diffuse peritonitis, which was confirmed by operation. An abscess in Douglas's pouch contained the appendix, which had a faecal concretion in its distal portion and a necrotic perforated area as large as a linseed. A counter opening in the left flank released a quantity of liquid pus, and Douglas's pouch was drained also. After several anxious days the patient improved. Sixteen days later an abscess as large as an apple was opened in the left iliac fossa; the patient improved and was discharged seven weeks after the operation. Two hours later she was readmitted with severe abdominal pain, rigidity, and bilious vomiting. After washing out the stomach and the passage of a long rectal tube peristalsis appeared to be restored and the bowels acted normally, but ten days later enterostomy was necessary, and a large mass of faecal concretions was evacuated. A month after her readmission the patient was again discharged, but the former symptoms returned, and fifteen days later the patient was admitted for the third time. Her condition was very serious, the pulse being 152 and small, and the abdomen distended; there was bilious vomiting and visible peristalsis. A tender swelling occupied the right iliac fossa. A second smaller abscess, lying between intestinal coils, was opened, but natural bowel action was not restored. Faecal vomiting followed and a second enterostomy was performed eight hours later. The patient progressed for two weeks, then the abdominal symptoms returned, accompanied by dysuria and pyrexia. Nineteen days later a small retroperitoneal abscess was opened; the pus contained *B. coli* and numerous streptococci. The patient improved until a spontaneous faecal fistula opened in the latest operation scar, but this healed naturally. Liek mentions other similar cases, and insists upon the necessity for systematic examination of the urine in every case of suspected appendicitis occurring during pregnancy.

46. The Early Diagnosis of Ectopic Gestation.

M. SABEL (*Med. Journ. and Record*, May 1st, 1929, p. 512) remarks that ectopic gestation is so varied in nature that at times other acute abdominal conditions, such as renal colic or acute peritonitis, may be closely simulated; this is particularly true when a double pregnancy—both intra- and extra-uterine—is present. The early and accurate diagnosis of the ectopic condition is of great importance, and the diagnostic aids most to be noted are: the history, with special reference to alterations in the menstrual cycle; pain in the lower abdomen as well as pain elicited after the sudden release of pressure on the abdomen; vaginal bleeding; intense sensitiveness on one side upon moving the uterus from side to side; and, in later cases, rapid increase in size of mass, associated with tenderness. Ectopic gestation is not common among coloured women, and it occurs most frequently at advanced ages. Sabel believes that previous abortions have an etiological significance, and the advanced age incidence support this belief, since there is thus time for tubal changes favouring ectopic gestation to develop. The menstrual history is a highly important point in diagnosis, and any alteration of the periodicity in conjunction with other signs is very indicative of an ectopic gestation. The most constant symptom is pain in the lower abdomen, which varies in degree; vaginal bleeding is the next most common symptom, but the amount is usually slight. The extreme sensitiveness of the unruptured tube is a very valuable sign. High temperature is usually evidence against extrauterine pregnancy, unless there is infection of the tubal sac: the pulse rate is in proportion to the temperature. Leucocytosis is generally present, but the red cell count and haemoglobin percentage are normal. A rapid sedimentation reaction is said to be more suggestive of pelvic inflammation than of ectopic gestation. Urinalysis is of no assistance as regards making the diagnosis, but the urine test for pregnancy is of definite value. Two cases are reported by the author: in one, owing to a criminal abortion having been induced, an erroneous diagnosis of acute peritonitis had been made; in the other a double pregnancy existed.

47. Carcinoma in Ovarian Dermoid Cysts.

J. C. MASSON and N. C. OCHSENHIRT (*Surg., Gynecol. and Obstet.*, May, 1929, p. 702) record three cases of squamous-cell carcinoma arising in dermoid cysts of the ovary and review thirty-three cases from the literature. Many reported cases were rejected because the evidence was insufficient to establish that the carcinoma actually developed within the dermoid, a condition only occurring in from 0.5 to 5 per cent. of the cases. The clinical differentiation of a benign dermoid cyst from one with early malignant degeneration is described as almost impossible until the carcinoma has so advanced as to penetrate the cyst wall or give rise to metastatic nodules in the adjacent organs. A certain diagnosis depends upon microscopical examination, and, consequently, all ovarian dermoid cysts should be carefully examined for malignant changes. Failing an absolute certainty as to its nature, an exploratory operation should be performed in every case of ovarian tumour; the prognosis is said to be grave unless early removal of the cyst is adopted. Malignant changes usually appear as a few areas of vegetation on the internal lining of the cyst, or as a thickening of its wall, but even on most careful examination early changes may escape notice. In the series of cases reviewed the longest duration of the presence of a tumour was nineteen years and the shortest six weeks.

48. Pregnancy following Amputation of Both Breasts.

CONTRARY to the view that there is some functional association between the breasts and the female genital organs, LEUNCKENS and PASTIELS (*Bruxelles-Méd.*, April 28th, 1929, p. 739) report a case indicating that the mammary glands apparently exert no influence on the utero-ovarian apparatus. A woman, aged 37, had phlegmonous inflammation of both breasts soon after her confinement; all varieties of local and general treatment were ineffective. The blood culture showed a staphylococcal infection. The breasts continued to inflame and suppurate, and amputation of the right breast was therefore undertaken to save the patient's life. The general condition improved, and the left breast was accordingly removed. Recovery was uncomplicated. The physiological results of the operation were awaited with interest. Menstruation was not affected in rhythm, duration, or regularity; the patient noticed faint prickings in the operation scars at the beginning of the menses. The genital feelings were unaltered. Eight months later the patient became pregnant and went to term without any noteworthy event. The accouchement was uncomplicated and the infant survived. The puerperium and the involution of the uterus were quite normal. Two later pregnancies occurred, but neither of these went to term. The authors, however, do not consider that the operation could have affected these remote events. They add that in animals a glycosuria has been noted immediately after amputation of the breasts; no glycosuria was reported in this patient.

49. Primary Syphilis of the Umbilical Vein.

Y. MANOUÉLIAN (*Gynécol. et Obstét.*, March, 1929, p. 161) records a case of primary syphilitic phlebitis of the umbilical vein, and emphasizes the necessity for care on the part of doctors and midwives lest they should be infected with syphilis. A woman, aged 28, who had previously had one miscarriage at the seventh month, and in whom the only possible syphilitic stigmata were scars on the shoulder and an osteophyte at a chondrosternal junction, went to term and had a labour which was normal save for a spontaneous tearing off of the umbilical cord at its placental attachment. The infant, although jaundiced, showed no morbid signs in the skin or mucous membranes. The cord had cicatrices on the surface and nodosities along the vessels; microscopically *Treponema pallidum* was demonstrated in great abundance in the blood of the umbilical vein, and also in the perivascular infiltration of polymorphs and macrophages. The infant died on the ninth day from haemorrhage from the umbilicus. The Wassermann test could not be performed on account of laking of the foetal blood, and no syphilitic lesions were detected on macroscopical or microscopical examination of the viscera. The author has previously described a case of primary syphilitic phlebitis in which both mother and child were apparently healthy at birth, but the umbilical vein was full of spirochaetes.

Pathology.

50. Bacteriophage Phenomena.

AFTER reviewing d'Herelle's work F. M. BURNET (*Med. Journ. of Australia*, March 30th, 1929, p. 405) discusses certain effects of bacteriophage phenomena that seem to have a bearing on disease; it has been shown that in most intestinal affections a phage, active against the infecting organism, is present in the intestinal contents at some period of the disease. Certain authors, particularly *Bordet, maintain that the appearance* of phage is due to the effect of the body defences on the infecting bacterium inducing a metabolic vitiation, but, according to the virus theory of d'Herelle, all phage is derived from pre-existent bacteria. It has been shown that a phage is not necessarily limited in its action to the one bacterial strain on which it has been isolated, but that a single phage may be active against two or more bacterial species, and that an originally weak phage may become much more active after it has been cultivated at the expense of some new organism. Closely related to this power of adaptation to a new organism is the question of the increase in virulence of the phage. This virulence is difficult to define, but its increase or decrease is easily recognized. If a phage is to be used therapeutically, it is advantageous to use one of the greatest activity. D'Herelle emphasizes this; he states that by using weak phages the infecting organism is enabled to develop a resistance against stronger phages, and with this resistance becomes more pathogenic. Certain factors tend to reduce the activity of phage *in vivo*, this being less than *in vitro*. In the body bacteria are in relatively smaller numbers than in broth cultures, and when in the tissues are multiplying in complex colloidal systems where there is little freedom of movement. Certain colloids actively inhibit lysis, and serum has a similar but less evident effect. Burnet concludes that the most reasonable view possible at present as to the importance of the bacteriophage in disease is that in those conditions, such as plague and typhoid fever, which are essentially or largely septicaemic, it plays but little part, and can be of therapeutic use only indirectly owing to its content of associated bacterial antigens. In infections such as bacillary dysentery and cholera, which are practically limited to the contents and lining of the alimentary canal, involving a body cavity rather than the tissues, a phage active against the pathogen usually develops, and may play a part in determining recovery. In this group the administration of active phage by the mouth is a rational therapeutic procedure.

51. Lactic Acid Excretion in Sport.

I. SNAPPER and A. GRÜNBAUM (*Nederl. Tijdschr. v. Geneesk.*, March 16th, 1929, p. 1358) examined the urine of 55 men who had played in football matches of two and three-quarter hours' duration on a warm day, and found more than 60 mg. lactic acid in 11 per cent., whereas after a game on a cold day 50 per cent. of the players showed more than 60 mg. lactic acid in the urine. In a match played on a warm day an average of 468 mg. lactic acid and 846 mg. chlorine was found in the players' shirts. The total loss of lactic acid in the sweat during the game was probably 1 to 2 grams. In a boat race extending over 2 kilometres and lasting six to eight minutes 28 of the 39 oarsmen showed more than 60 mg. lactic acid in the urine, and 95 mg. lactic acid and 84 mg. chlorine in their shirts. In foot races of 3, 5, 10, and 42 kilometres, lasting between nine minutes and about two and a half hours, little lactic acid as a rule was found in the urine. In swimming, on the other hand, much lactic acid was usually found in the urine, not only in the 400 metre races lasting five minutes, but in the 1,500 metre races lasting twenty to twenty-two minutes, and the water polo matches lasting seven and a half minutes. Albuminuria was rarely found after football matches, foot races, or rowing in the case of trained sportsmen, but was very frequent in swimmers.

52. Carbohydrate Metabolism and the Ovarian Hormone.

E. KAUFMANN (*Deut. med. Woch.*, April 19th, 1929, p. 650) has investigated the effect of ovarian hormone in several diabetic women a few years after the menopause; they had all been under observation for some years, and their metabolism was comparatively stable. One who was very refractory to insulin was given one tablet of progynon (250 mouse units) daily, the dose being subsequently raised to 500 mouse units. Though the vasomotor symptoms and neuritis improved, glycosuria and blood sugar increased. In another similar case menformon folliculin was injected with insulin for one month, the dose of the ovarian preparation being gradually increased from 20 to 80 mouse units; the combined treatment again had a deleterious effect on carbohydrate metabolism. Kaufmann disagrees with Bauer, Flata, Zondek, and others who consider that the pancreas and ovaries affect carbohydrate metabolism in the same direction, though differing in manner and degree, and counteract the thyroid, pituitary, and chromaffin systems in this respect; he concludes that the ovarian secretion antagonizes insulin in its action on metabolism in diabetes, and suggests that this may be one of the reasons why children (in whom the sex glands are not functioning fully) are particularly liable to hypoglycaemic symptoms. It may also account for the variations in carbohydrate metabolism associated with the menstrual cycle and occurring during pregnancy in the diabetic and non-diabetic. The great risk of hypoglycaemia during the puerperium in diabetics on insulin which has been reported may also be partly due to a sudden diminution in the circulating ovarian hormone. The return of menstruation as a result of insulin treatment in diabetes with amenorrhoea must not be regarded as evidence of synergism between insulin and ovarian hormone, but is probably due to a general improvement in the metabolism.

53. Action of Saponin upon Intestinal Absorption.

N. ENDO, T. MIZOGUCHI, and K. NAITO (*Japan Med. World*, February 15th, 1929, p. 35) report a series of investigations on mice relating to the way in which the oral administration of saponins (toxic nitrogen-free glucosides contained in such preparations as sarsaparilla) raises the degree of absorption of the intestinal canal for certain substances. Koller and Kaurek, in 1925, found that strophanthin and digitoxin are absorbed much more rapidly if administered with saponin, and this has been shown by other observers to be true also in the case of calcium, curare, glucose, aspirin, and pituitary extract, but not in the case of thymol, camphor, and veronal. The present authors found that various chemical substances, such as magnesium sulphate and reduced iron, become very toxic to mice when mixed with saponin, and a similar result followed where certain bacilli and serums were concerned.

54. Resistance of the Diphtheria Bacillus.

DURING an examination of 10,000 throat swabs P. LOMRY (*C. R. Soc. de Biologie*, May 17th, 1929, p. 161) made some observations on the resistance of the diphtheria bacillus. He finds that after an attack of diphtheria 90 per cent. of patients remain carriers for five or six weeks, 9.9 per cent. (? 9.1) for three to four months, and 0.9 per cent. for one to two years. Though it is not unusual to find that the bacilli in the throats of chronic carriers are fully virulent, the author considers that as a rule the virulence diminishes progressively. On artificial media, provided subcultures are made sufficiently often, the virulence remains high indefinitely. Inoculated into water from various sources—rain, well, river, pond, snow—contained in test-tubes, the diphtheria bacillus remains alive for three days at room temperature and for thirty hours in an incubator. The result is the same whether the water is used fresh or is previously boiled. Dried on pieces of fabric, wood, or metal, and kept in the light or in the dark, the bacilli live for about fifteen to twenty-five days. This time is not diminished by exposing them in a room submitted to formalin fumigation. Before actually dying, bacilli which are undergoing desiccation are stated by the author to decolorize with Gram's method, to lose their power of fermenting glucose, and to become practically avirulent. As a practical conclusion from these observations, the author states that disinfection of rooms after diphtheria, other than by washing, is not of sufficient value to be justifiable.

55. Anaerobic Organisms in Otitis.

P. C. MONTI (*Arch. Ital. Otolog.*, March, 1929, p. 185) reports observations on 25 cases of purulent otitis media, both subacute and chronic, and with and without endocranial complications. The object of the investigation was to discover whether any of the organisms found in the pus of the ear were true anaerobes. Surrounded and penetrated as the auditory apparatus is by the atmosphere, and influenced by the movements of respiration and deglutition, it was not surprising to find that as a result of this investigation no strict anaerobes were found in the pus. The pus was diluted with sterile broth, plated on alkaline glucose agar and milk agar, and incubated for two to seven days. All the organisms isolated from the anaerobic cultures successfully lived aerobically on subculturing. The principal anaerobes found were Gram-negative cocco-bacilli and Gram-positive spore-bearing rods; all these proved to be facultative anaerobes. Some investigators have found strict anaerobes in certain auditory affections, and the present author suggests that strict anaerobes in the presence of living tissue may live in a state of symbiosis with aerobes. Since these conditions are not artificially reproduced in culture, only facultative anaerobes appear.

OF DEFINITE VALUE IN THE PROMOTION OF SLEEP

AS SUPPLIED TO H.M. THE KING

BY APPOINTMENT
Wire Mattress and
Bedstead Manufacturers
to H.M. THE KING

There is one physic which never fails of its purpose—sleep. A Staples Mattress will not ensure it, but is of definite value in promoting it. The reason is simple—the lithe steel springs afford *equal support to all parts of the body*—thus the muscles are fully relaxed and the nerves automatically follow suit—sleep is naturally *induced* with the Spine Straight and the internal and digestive organs undistorted.

Sold by ALL Furnishers 3ft. 99/-, 4ft. 6ins. 118/6

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely di[illegible] narantee and service system.
6. It is suitable for [illegible]t.
7. It is helpful for [illegible], office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

WELCOME TO STAND 96 B.M.A. MEETING.

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Sensitiveness!

The necessity of wearing a Colostomy Appliance is in itself a source of embarrassment to the patient—physically and mentally.

All undue apprehension on the part of the patient, however, is largely overcome by the personal comfort and sheer hygiene afforded by the

"SALTS"
PATENT COLOSTOMY BELT

which has the following advantages:—

1. Rubber container has no crevices or vulcanite fittings, so that unpleasant odour is reduced to a minimum.
2. Cup and bag of moulded rubber readily sterilised by boiling.
3. Bag immediately removed for emptying and washing purposes without removing Belt.

COPYRIGHT. ESTABLISHED 1793

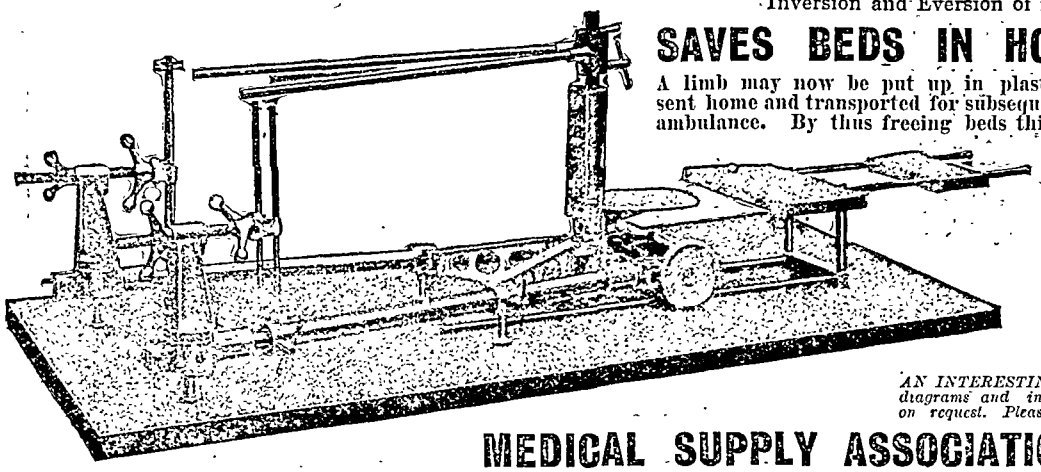
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 14 in. × 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS, NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairtechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

By Order of the Council,
J. BERNARD LAMB,
July 8th, 1929. Secretary.

University of Birmingham.

APPOINTMENT OF LECTURER IN PHYSIOLOGICAL DEPARTMENT.

Applications are invited for the post of Lecturer in Physiology. Stipend £400 per annum. Four copies of application, with copies of testimonials, must be sent, on or before August 5th, to the undersigned, from whom further particulars may be obtained.

The University, Edmund Street, Birmingham. July, 1929. C. G. BURTON, Secretary.

Preliminary Examinations.

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1

D.P.H.Camb. & Lond., B.Sc., M.D., M.R.C.P.,

prepares candidates for Degrees or Diplomas in Hygiene. Experienced as Lecturer, Demonstrator, and Tutor. Typed notes. Many successes.—Address, No. 4320, B.M.A. House, Tavistock Square, W.C.1.

Lowestoft and North Suffolk HOSPITAL.

HOUSE SURGEON (male) preferably with knowledge of X-ray. Salary £120 p.a., with board, residence, and laundry.

Applications, with copies of three recent testimonials, to the Honorary Medical Supt

London Jewish Hospital,

Stepney Green, E.1.

Applications are invited (and should be sent to the Secretary immediately) for the post of OUT-PATIENT ASSISTANT for the months of August and September. Honorarium at the rate of £50 per annum.

Malayan Medical Service.

VACANCIES FOR ASSISTANT MEDICAL SUPERINTENDENTS IN MENTAL HOSPITALS AT SINGAPORE AND TANJONG RAMBUTAN.

Qualifications.—Applicants, who must be British subjects of European parentage and not over 35 years of age, should have been Resident Medical Officers at an Asylum or other Institution for Mental Diseases for not less than one year.

Salary.—$500 per mensem (£700 per annum), rising by annual increments of $25 per mensem (£35 per annum) to $550 per mensem (£770 per annum). Officers are appointed on probation for a period of three years and then become eligible for confirmation, after which the salary rises by annual increments of $25 per mensem (£35 per annum) to $800 per mensem (£1,120 per annum).

Allowances.—In addition to salary, there is at present a temporary non-pensionable allowance of 10 per cent. of salary to unmarried officers and 20 per cent. to married officers.

Currency.—The Straits dollar is equivalent to 2/4 of English currency. The rate is liable to alteration but has remained unchanged for many years past; so far as can be foreseen, no change is anticipated.

Passages.—Free first-class passages are provided both on first appointment and on leave.

Quarters.—Free quarters with heavy furniture are provided.

Further particulars and forms of application may be obta[illegible] riting, to the Private Secretary, Colonial Office, 2, Ric[illegible] S.W.1.

Egyptian Government.

EGYPTIAN UNIVERSITY.

Applications are invited for the post of PROFESSOR OF CLINICAL PATHOLOGY.

The salary offered is £E.1,500 (about £1,530) a year without pension, and the appointment will be on contract for five years, but may be renewed by mutual consent for a further period.

The Professor of Clinical Pathology will be expected to organize the work of the Department of Clinical Pathology in its relation to the Kasr-el-Aini Hospital and to give such courses of instruction as may be decided upon. Preference will be given to candidates possessing a special knowledge of diseases of warm climates. The appointment is to be a full-time post, no private practice being allowed.

An allowance equal to one month's salary will be paid on arrival at Cairo for travelling expenses.

Applications, accompanied by testimonials and references, to be addressed to the Dean, Faculty of Medicine, Egyptian University, Cairo, so as to be received not later than September 15th, 1929.

British Red Cross Society's [illegible]F PARK PARK.

There is a vacancy for the post of MEDICAL SUPERINTENDENT (Non-resident). It is hoped that the building will be ready for patients by November 1st next, but the duties of the Medical Superintendent will begin in September, as he will be expected to help in the preparation for the reception of patients, who will be Out-patients only. After the Clinic is opened his duties will be to see that treatment prescribed by the staff is properly carried out and to supervise the general administration of the Clinic. Applications may be accompanied by not more than two testimonials (copies). Salary £600 a year payable quarterly. The initial appointment will be for one year, but may be renewable.

Applications to be sent to the Secretary of the Clinic Committee, British Red Cross Society, 19, Berkeley Street, London, W.1, not later than July 24th next.

The Willesden General Hospital, N.W.10.

SURGICAL OUT-PATIENTS' DEPARTMENT. CLINICAL ASSISTANT.

GYNÆCOLOGICAL OUT-PATIENTS' DEPT. CLINICAL ASSISTANT.

Applications are invited for each of the above appointments for a period of six months from August 1st. The successful applicants will be expected to attend the Hospital regularly and to take charge of the Department when the Medical Officer is absent.

Applications should be addressed to the undersigned not later than Wednesday, July 17th, from whom full particulars of each appointment can be obtained.

R. J. HEARNE, Secretary.

City of Manchester.

APPOINTMENT OF ASSISTANT TUBERCULOSIS OFFICER.

The Public Health Committee invites applications for the position of Assistant Tuberculosis Officer at a commencing salary of £650 per annum, rising by annual increments of £25 to £750 per annum. (First increment January 1st, 1931.)

Applications, stating age, qualifications, and experience, to be forwarded to the undersigned as soon as possible.

JOHN GIBSON,
Superintendent and Secretary.

Royal Infirmary, Preston.
June, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
			150	1st
Lieut.		500	150	2nd
			150	3rd
			150	4th
Capt.	(i) During first 3 years' service as Captain	650	£15	5th
			£15	6th
			£25	7th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	8th
			£25	9th
			£25	10th
	(iii) With more than 6 years' service as Captain	850	£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1929. Applications should reach the War Office not later than July 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LIVERPOOL.—Centrally situated old-established PRACTICE. Income about £1,500. Panel of over 2,500, worked from Branch Surgery. Visits and medicine from 3/6 to 7/6. Little midwifery. Large corner house, with garden and garage. Recently redecorated. Electric light and new hot water system throughout. Price, freehold, £2,000. Large scope for increase. Premium 1½ years' purchase.
2. GLOS.—LARGE TOWN.—PARTNERSHIP.—A half share of an old-established good-class non-dispensing Practice, owing to retirement through ill health of senior partner. Income about £5,000, with small select panel. Fees 5/- to 10/6. Purchaser should be about 40, married, and keen on midwifery. Good house available at low rental. Premium 2 years' purchase, part by instalments.
3. NEAR HARROGATE.—UNOPPOSED COUNTRY PRACTICE.—Income for last year over £500, but has done about £1,500. Visits and medicine 3/6 to 10/6. Little midwifery. Large house in 7½ acres of ground. Excellent sport of all kinds. Price, freehold, £2,000. Premium, including drugs, etc., £550.
4. KENT.—FAVOURITE COAST TOWN.—PARTNERSHIP.—A one-third share (to commence) in an old-established non-dispensing chiefly better-class Practice, averaging, for the past three years, over £3,000 p.a. Fees 5/- to 21/-. Only about 10 midwiferies at from 3 to 10 gns. Very good house with 4 reception, 6 bedrooms, usual offices. Garden. Large garage. Price for freehold £3,000, half on mortgage. Premium 2½ years' purchase.
5. SURREY.—HOSPITAL TOWN.—PARTNERSHIP.—A one-fourth share, (to commence) in an old-established good mixed Practice. Average gross cash receipts £4,400, including panel of 2,000 and appts. worth £500 p.a. Fees 3/6 to 21/-. Suitable house. Premium 2 years' purchase. Purchaser should be about 30 years of age and a good surgeon.
6. SOUTH-WEST COUNTY.—PARTNERSHIP.—Good residential district, near large town.—A one-fourth or one-third share (with increase up to one-half later) is for disposal in an old-established and steadily increasing Practice. Average gross cash receipts for past three years over £3,000, of which £900 is from panel and about £100 from appts. Fees 3/6 to 42/-. Cottage Hospital and good scope for surgery. Choice of two houses. Premium 2 years' purchase.
7. NEAR BATH.—Old-established unopposed country PRACTICE, held by Vendor 10 years, and situated in an attractive district within easy reach of two good towns. Cash receipts for 1928 £656, and this year at rate of £700. Panel of over 500. Fees 2/6 to 12/6. Large house with 6 bedrooms, etc., and an acre of garden and paddock. Price for freehold £1,200. Premium £900.
8. LONDON, NORTH.—RESIDENTIAL SUBURB.—Good middle-class PRACTICE. Income for last year over £700, with ample scope. Small select panel of nearly 300. Fees 2/6, 3/6, and 5/-. No midwifery. Excellent detached corner house, with electric light. Garden. Garage. Price for leasehold (75 years) £1,750. Premium 1½ years' purchase.
9. KENT.—COAST TOWN.—Well-established mainly industrial PRACTICE. Steady average income of over £1,560. Panel of 1,350. Advice and medicine mainly 3/- and 5/-, a few at 7/6. Visits and medicine 3/6 to 7/6, a few at 15/- and 21/-. Convenient house, with 5 bedrooms, on lease (9 years), rent £100 p.a. Premium 1½ years' purchase.
10. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE. Income about £1,000, but has been much more. Fees 5/- to 21/-. Little midwifery. Large well-situated house freehold. Excellent schools and sport. Good hospital. Practice very easily worked. Price for house and Practice £4,000.
11. BLACKPOOL.—Well-established better and middle-class PRACTICE. Income last year over £1,200. Panel of 556. Fees from 2/6 to 4/-. Little midwifery. Good house in quiet residential district. Price, freehold, £2,700. Premium 1½ years' purchase, £1,000 cash and balance by instalments.
12. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE.—Large Hospital Town within 80 miles of London. A well-established connection averaging nearly £1,000 p.a. (last year £1,059). Patients upper and middle-class. Fees 1½ to 15 gns. House in pleasant position, with ample professional accommodation. Rent £60. Premium £1,500, or offer. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital and successor will be appointed.
13. LIVERPOOL.—Mixed-class PRACTICE, producing this year at the rate of over £1,200. Panel of 560. Good house specially built and well situated, containing 2 reception, 4 bedrooms, etc. Large garden. Garage. Price for leasehold £1,800, part on mortgage. Prem. £1,650.
14. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a man possessing the F.R.C.S. Receipts for [illegible] average over £5,000 p.a. Good house, with [illegible] at present held on lease with option to purchase. Premium 2 years' purchase.
15. NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, mileage extra. No dispensing. Excellent Bungalow, in an acre of garden, tennis court, etc., 9 rooms, bathroom, etc. Electric light. Splendid educational facilities and unlimited sport. Scope for surgery.
16. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established good mixed non-panel Practice, offering large scope. Receipts for last year nearly £2,300. Fees 2/6 to 7/6. Little midwifery. Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
17. CARDIFF.—Good-class old-established non-dispensing PRACTICE, worth last year about £1,350, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, freehold, £2,000. Prem. £2,000.
18. MIDLANDS.—Country District near large Town.—Agricultural and working-class PRACTICE, rapidly increasing. Income last year £1,250, including panel of 545. Visits 3/6 and 5/-. Small convenient house, with large garden and garage. Price freehold (including all furniture excepting linen and plate) £1,650 (£1,000 on mortgage at 4 per cent.). Excellent sport. Premium £1,800.
19. SOUTHAMPTON.—Old-established mixed-class PRACTICE. Average gross cash receipts for past 3 years £1,535, including panel and appts. worth about £850. Visits 3/6 to 10/6. Practically no midwifery. Exceptionally nice house, with ample accommodation and garden. Price £2,000. Premium 1½ years' purchase.
20. EAST COAST.—SEAPORT TOWN.—Old-established middle and working class PRACTICE. Average cash receipts for the past three years £1,835, including panel of over 1,000. Fees 2/6 to 10/6. Midwifery has been discouraged, but much can be had at fees from 5 gns. upwards. Good house with 2 reception, 5 bedrooms, etc. Electric light. Small garden. Price for freehold £1,350, part on mortgage Premium 1½ years' purchase, part by instals. Ill health reason for sale.
21. SOUTH [illegible]V.—PARTNERSHIP.—A one-fifth share in [illegible] producing about £5,000 p.a., including [illegible]ry good house, with 2 reception, 5 bedrooms, etc., and usual offices. Rent on lease £45 p.a. Well-equipped Hospital. Premium 2 yea[illegible]
22. SOUTH COAST. — Popular and [illegible] Old-established increasing mixed-class [illegible] year nearly £1,600 (this year to end [illegible] panel of over 1,150. Visits 3/6 upwar[illegible] cases yearly). House contains eight rooms, with usual offices and garden. Price for freehold £1,450 (£1,000 at least obtained on mortgage). Premium 1½ years' purchase.
23. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 3/- upwards. Not much midwifery. Low expenses. Very well-situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional rooms. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
24. EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP.—A one-third share in a very sound mixed-class Practice, producing £2,300 p.a., and offering excellent scope. Panel of about 1,000, and good appointments. Choice of houses. Premium 2 years' purchase.
25. MANCHESTER.—PRACTICE is situated in a growing district offering very good scope. Income for the immediate past 12 months over £1,600, including panel of nearly 900. Fees 3/6 upwards. Detached well-situated house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £110 p.a. Premium 1½ years' purchase.
26. WEST END.—Good-class non-panel and non-dispensing PRACTICE established many years. Average cash receipts for past three years nearly £1,400. Fees one guinea. Suitable accommodation available. Premium £2,000. Good introduction. Ill health reason for sale.
27. EASTERN SUBURB.—PARTNERSHIP, with succession.—A half-share in an old-established Practice averaging over £1,100 p.a., including panel of 1,145. No midwifery, but scope for this. Suitable house, with electric light and garden. Price £800. Premium 2 years' pur.
28. EASTERN COUNTIES. — Unopposed Country PRACTICE, easily worked, and situated in beautiful district, near two good towns. Average cash receipts for past three years £1,064, including panel of 530. Nice house, with 3 reception, 6 bedrooms, etc. Price for freehold £2,000. Premium £1,500.
29. LONDON.—EAST END.—Increasing cash and panel PRACTICE producing £450 p.a., including 300 panel patients. Visits 3/- upwards. Very little Midwifery. Seven-roomed house on lease. Rent £78, inclusive of rates and taxes. Premium £650.
30. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. Premium 1½ years' purchase. Exceptionally good educational facilities for boys.

Full Schedule of Terms and Conditions will be forwarded on application.

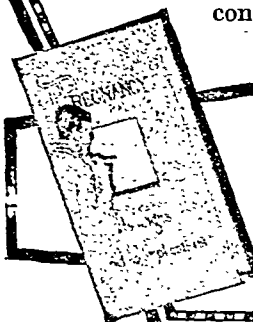
RELIEF!—*Nothing Else Matters!*

When confronted with *abdominal pain*—in the host of inflammatory conditions peculiar to pregnancy—in cases of *acute gastroenteritis, gastralgia, enterocolitis* and *chronic mucous colitis*, physicians find that relief of local discomfort comes more rapidly when

Antiphlogistine

is used as an adjunct to the general treatment. Applied in hot, thick layers to the abdomen and liver area, this simple procedure has an active influence over not only the amount and character of the bile that is secreted, but upon the production of the digestive juices generally. Leading practitioners everywhere confirm the beneficial results obtainable with this *standard* poultice and dressing in many types of inflammatory conditions, both superficial and deep-seated.



The Denver Chemical Mfg. Co.,
London, E.3.

Dear Sirs: You may send me a complimentary copy of your booklet "Pregnancy —Its Signs and Complications" (sample of Antiphlogistine included).

'BYNIN' AMARA

(TRADE MARK)

A Powerful Tonic and Hæmatinic

'Bynin' Amara is of special value in influenzal conditions and in the marked asthenia and nervous depression which are prominent features of the post-influenzal state. A course of 'Bynin' Amara whenever there is any indication of lowered resistance is a valuable safeguard against infection.

It has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

In bottles at 3/6, 6/6 and 12/-

Further particulars and free sample will be sent on request

Cascara Evacuant

CASCARA Sagrada was introduced to the medical profession by Parke, Davis & Company in 1877. Since that time the tonic laxative action of preparations of the bark has earned for cascara the designation of "the ideal laxative."

Ordinary preparations of cascara are bitter, but in Cascara Evacuant, Parke, Davis & Company have succeeded in presenting an active tonic laxative without the principle to which the bitter taste is due.

Cascara Evacuant (P., D. & Co.) is a most palatable *active* preparation of cascara and is not fortified by admixture with other laxative drugs.

Cascara Evacuant (P., D. & Co.) may be prescribed in doses of from 10 to 30 minims in a little water, thrice daily. Supplied in bottles of 1-1/2, 4, 8, 16 and 80 fluid ounces.

PARTIAL CONTENTS

ALIMENTARY TRACT

Retrograde Dilatation of the Esophagus for Cardiospasm
Degree of Malignancy of Carcinoma of Esophagus
Early Cancer of Stomach
Roentgenologic Diagnosis of Gastric Ulcer
Roentgen Ray in Determining Resectability of Gastric Cancer
Two-stage Operations for Carcinoma of Stomach
Division of Vagi for Pylorospasm
Vascular Studies of Pylorus
Benign Tumors of Duodenum
Results of Accumulations of Bile Around Liver
Jaundice and Ascites in Diseases of Liver
Portal Cirrhosis with Chronic Inorganic Arsenical Poisoning
Structure and Arrangement of Bile Canaliculi
Respirator Quotient and Basal Metabolic Rate Following Removal of Liver and Injection of Glucose
Cholecystography
Relief of Obstructive Jaundice from Tumors in Head of Pancreas
Strictures of Common and Hepatic Bile-ducts
Removal of Stones from Common and Hepatic Bile-ducts in Jaundiced Patients
"Sidetracking" Operations in Obstructive Jaundice
Prolonged Drainage of Common Duct
Fibrosarcoma of Jejunum
The Nature and Treatment of Toxemia of Intestinal Obstruction and Ileus
An Aseptic Method of Intestinal Anastomosis
Repair of Incisional Hernia
Diagnosis of Amebiasis
Incidence of Amebiasis and Its Relation to Carrier Problem
A Clinical Consideration of Endamebiasis
Treatment of Endamebiasis
Experimental Studies on Diphyllobothrium Latum
Tetany and Chronic Diarrhea
Changing Conceptions of Chronic Ulcerative Colitis
Chronic Ulcerative Colitis Associated with Malignant Disease
Perforations of Colon in Ulcerative Colitis
Specific Serum Treatment of Chronic Ulcerative Colitis
Cooperative Management of Surgical Diseases of Colon
Intraperitoneal Vaccination in Carcinoma of Colon by Mixed Vaccine of Colon Bacilli and Streptococci
Surgical Procedures in Carcinoma of Large Bowel
Factors of Safety in Operations for Carcinoma of Colon
Mikulicz Operation for Resection of Colon
Megacolon
Technic of Anterior Resection of Rectosigmoid
Colloid Carcinoma of Colon and Rectum

GENITO-URINARY ORGANS

Treatment of Nephritis and Nephrosis with Edema
Diuretic Action of Nitrates in Dropsy
Surgical Lesions of Kidney
Stricture of Ureter
Tuberculosis of Genital Tract
Surgical Treatment of Malignant Tumors of Bladder
Epithelial Neoplasms of Urinary Bladder
Pyuria in Chronic Uncomplicated Prostatitis
Present Status of Prostatic Punch Operation
Suprapubic Prostatectomy
Radiotherapy for Tumors of Testis
Irradiation of Ovaries and Hypophysis in Disturbances of Menstruation
Radium in Treatment of Menorrhagia of Adolescence and of Menopause
Carcinoma of Fundus of Uterus
Hematometra
Fistula of Uterus
Radium in Carcinoma of Cervix
Cystic Cervicitis, with Special Reference to Treatment by Cauterization
Dental Hygiene During Pregnancy
Treatment of Diabetes During Pregnancy
Significance of Nephritis of Pregnancy
Carcinoma of Breast

DUCTLESS GLANDS

Blood Pressure of Patients with Diabetes Mellitus
Obesity as Precursor of Diabetes
Synthalin, Myrtomel, and Glukhorment
Tumor of Islets of Langerhans with Hyperinsulinism
The Thyroid Problem
Seasonal Variations in Iodine and Thyroxin Content of Thyroid Gland
Function of Thyroid Gland Containing Adenomatous Tissue
Exophthalmic Goiter
Oxygen Treatment After Thyroidectomy
Diseases of Children Benefited by Splenectomy
The Splenomegalias

BLOOD and CIRCULATORY ORGANS

Coronary Arterial Disease
Heart-block Showing Multiple Transitions Associated with Convulsive Syncope
Course of Syphilitic Cardiovascular Disease
Ophthalmoscopic Signs in Diseases of the Heart
Hypertension in Young
Studies in Blood Volume with Dye Method
Blood Volume Preceding and Following Splenectomy in Hemolytic Icterus and Splenic Anemia
Clinical Applications of Photo-electric Photometry to Measurement of Hemoglobin
Sedimentation of Erythrocytes
Reduction of Hypercalcemia in Polycythemia Vera by Phenylhydrazine
Quantitative Pettenkofer Test to Determine Bile Acids in Blood
Enterohepatic Circulation of Bile Acids

SKIN AND SYPHILIS

Purpuric Skin Manifestations Following Use of Metbaphen
Krysolgan in Lupus Erythematosus
Sarcoids and Related Lesions
Treatment of Neurosyphilis by Malaria: Serologic Results and a Comparison with Treatment by Typhoid Vaccine
Bismuth Arsphenamine Sulphonate: A New Synthetic Drug for Use in Syphilis

HEAD, TRUNK, EXTREMITIES

Lynch Type of Radical Frontal Sinus Operation
The Eye in Leukemia
Foreign Proteins in Treatment of Eye Diseases
Treatment of Malignant Lesions of Eyelids
Effect of Otitis Media in Cases Previously Operated on for Mastoiditis Rhinoscleroma
Total Rhinoplasty
Factors in Decay of Teeth
Multilocular Lymph Cysts of Neck in Children—Radium
Local Anesthesia for Operations on Neck
A Two-stage Laryngectomy
Blastomycosis of Larynx
Operative Fusion for Tuberculosis of the Spine
Congenital Pseudarthrosis of Tibia
Early Differential Diagnosis of Gout

CHEST

Bronchoscopy in Diagnosis of Malignant Conditions of Liver
Capillary Bronchitis: Administration of Oxygen
Oxygen in Postoperative Bronchopneumonia
Oxygen in Postoperative Treatment
Respiratory Reserve
Phrenicotomy in Diaphragmatic Hernia and Tumors of Chest Wall

BRAIN, CORD, AND NERVES

Tumor of Frontal Lobe Presenting Parkinsonian Syndrome
Incisura of Crus Due to Contralateral Brain Tumor
Meningitis Due to Micrococcus Catarrhalis
Streptococci in Spinal Fluid in Acute Epidemic Poliomyelitis
Iodized Oil in Diagnosis of Lesions of Cord
Serum Treatment of Poliomyelitis
Raynaud's Disease of Upper Extremities: Successful Treatment by Resection of Sympathetic Cervicothoracic and Second Thoracic Ganglia and Intervening Trunk
Postanesthetic and Postoperative Psychosis
Ketogenic Diet Treatment of Epilepsy in Adults
Hereditary Type of Angioneurotic Edema
Clinical Phenomena Associated with Depressions, Anxieties, and Other Affective or Mood Disorders

MISCELLANEOUS

Dietetics from Viewpoint of the Physician
Focal Infection in Chronic and Recurring Diseases
Insurance as Factor in Health Betterment
Preventive Medicine
Coördinating the Relations of Laboratory and Clinical Staffs
William Worrell Mayo
Bronchogenic Squamous-cell Carcinoma
Ultraviolet Light, Insulin, and Amino Acid Catalysts
Graphite Preparation for Intravital Staining
Nonmelanotic Melano-Epitheliomas and Their Relation to Melano-Epitheliomas
A Roentgenologic Consideration of Endothelial Myeloma
Cancer: Cure or Console
Systemic Histamine-like Reactions in Allergy Due to Cold
Localization of Bacteria in Tissues of Lowered Resistance

Octavo volume of 1197 pages, profusely illustrated. By WM. J. MAYO, CHARLES H. MAYO and their Associates at the Mayo Clinic, Rochester, Minn., and The Mayo Foundation, University of Minnesota. Cloth 60s net.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street LONDON, W.C.2

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Refer your Patients also to

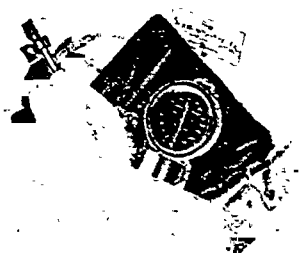
LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

As Necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade-mark "Tycos" engraved on the dial.

Obtainable from all reputable Instrument Dealers.

Tycos **SHORT & MASON LTD.**

Even the weakest patients, with virtually no energy to digest food of any kind, can frequently assimilate and retain Horlick's when all other foods are rejected.

Prospective Students of Medicine

FOR the guidance and assistance of those wishing to enter the Medical Profession, and for those already qualified who are desirous of planning a career, it has been decided to publish, on

August 31st,

a

Special Educational Number

of the

British Medical Journal

THIS Number will contain full information regarding Medical Education and the fees charged by the teaching and examining bodies in England, Scotland, and Ireland. Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

DEBTS COLLECTED "WITHOUT OFFENCE"

The following Testimonial recently received fully substantiates the claims made by the Society in connection with their ability to collect unpaid fees on behalf of the Medical Profession:—

66, The Crossways,
Gidea Park, Essex.
3rd June, 1929.

Dear Mr. Watson,

Very many thanks for your Statement, Report and Cheque. I am delighted with the results; also with the manner in which the collection has been carried out.

It affords me very much pleasure to pen this note, and I shall be pleased to recommend you.

You may make what use you like of this letter.

With kind regards,
Yours faithfully,
ARTHUR R. SOADY,
L.R.C.P.I., L.M. & L.R.C.S.I.

Let us do the same for you and save you the worry and annoyance of debt collection, which is specialised work in which the British Medical Protection Society has been interested for forty years, with very excellent results. The policy is to collect Overdue Accounts "WITHOUT OFFENCE" and thus ensure that good feeling which is so essential between Doctor and Client.

Full particulars of terms, etc., will gladly be furnished on application to the

BRITISH MEDICAL PROTECTION SOCIETY
(B.M.P.S., Ltd.)

'Phone MUSEUM 4228.

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories £350

Ditto, Apparatus for use on Direct Current £410

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

SEND FOR DESCRIPTIVE CATALOGUE No. E12

Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY X-RAY APPARATUS

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

THE Immediate delivery from stock. Sole Manufacturers:

Electrocardiograph without case

CAMBRIDGE PORTABLE CARDIOGRAPH

Electrocardiograph in case

A novel form of film camera enables four films (6¾ × 3¼ inches) to be exposed in three sections in the normal way, without using a dark room. Non-immersion electrodes are used. The source of light is a 12-volt lamp. The outfit, including the battery, is contained in compact carrying cases.

This apparatus is similar in principle to the standard Einthoven electrocardiograph (and produces exactly similar records), but is arranged in a portable form, so that it may be easily taken to a patient's house.

THE
ARNOLD "CLEARLITE" FOREHEAD LAMP

giving that perfect illumination which is essential to the Surgeon in all his work.

The advantages of the CLEARLITE LAMP.

(1) Light and comfortable, being made of aluminium.
(2) Fitted with rubber sponge pads and screw adjustment, which makes it adaptable to all heads.
(3) Remains firmly in position during all movements of the head.
(4) A vulcanite connection in the flex allows the surgeon to move away without disconnecting leads from battery.
(5) The special gas-filled bulb ensures a clear circular disc of light.
(6) The "Clearlite" may be focussed on the smallest point for examination.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine Sparkling Pine Bath Tablets

for nervous & heart disorders, rheumatic conditions, etc., etc.

This preparation is now obtainable in 5-oz. bottles.

MIST. HEPATICA CONC. (Hewlett's).

Composition.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.
This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz; and 90-oz. Bottles. Price in England, 12/6 per pound.
This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

Affords relief in all cases of high blood pressure

The daily exhibition of Sal Hepatica, the non-habit forming saline purgative, has proved of extreme benefit in all cases of high blood pressure. ¶ Sal Hepatica is also recommended as a rapid means of relieving the stress in cases of dysmenorrhea. One or two drachms administered on the morning before the expected period, and again at its outset, rarely fails to relieve both the pain and depression. ¶ In chronic constipation the regular exhibition of Sal Hepatica for a week or two restores the daily habit of defecation. ¶ Sal Hepatica is not a "patent medicine" and is only advertised to the medical profession.

Sal Hepatica

the proved medical saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

BRISTOL-MYERS COMPANY, 112, Cheapside, London. E.C.2

Intestinal Disinfection

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

In 20 cases of Whooping Cough, relief from spasm and vomiting occurred in 18 of the patients.

Price: 4/6 per 8-oz. bottle; 16-oz., 18/-.

FULL LISTS ON APPLICATION.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and CO. LTD.

K.Y. LUBRICATING JELLY

K.Y. Lubricating Jelly reduces the discomfort of instrument-introduction far more efficiently than petrolatum. It is more "slippery," flows more easily, and never binds. It is contained in a convenient compressible tube, which protects it from the air and enables the exact amount needed to be squeezed out quickly and hygienically. K.Y. Jelly is greaseless, non-staining, and water soluble. It is prepared from certain vegetable substances blended in correctly balanced proportions with boric acid, and does not irritate the skin or interfere with the application of local remedies.
Obtainable from medical supply firms and pharmacists throughout the world.
Write for samples, stating name of your local supply house.

INSULIN "A.B."

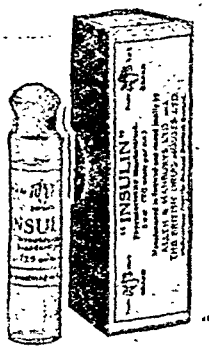
TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/- each
10 c.c. (200 „ 20 „) 4/- „
25 c.c. (500 „ 50 „) 10/- „

40 units per c.c.

Packed in bottles containing:

5 c.c. (200 units or 20 doses) 4/- each

Full particulars and the latest literature will be sent free to members of the Medical Profession.

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol": (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

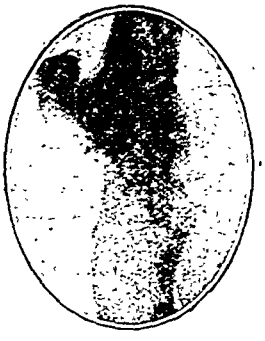
'IODOLYSIN'

Trade Mark

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



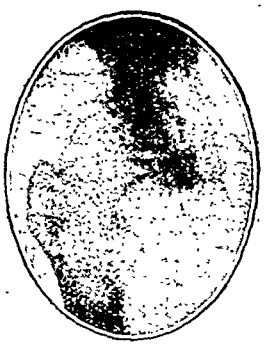
Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.



Radiograph of Hip-joint in Rheumatoid Arthritis

Free Clinical Sample and Literature on request

AUTOTOXAEMIA in Mental Psychoses

—mens sana in corpore sano—

The *Vis insita* and the *Vis nervosa* of cells have a common source of nutrition, but it is certain that the latter is more easily injured (or killed) than the former in various types of autotoxaemia and faulty metabolism.

Mental Alienists of to-day emphasize the all-important influence of gastro-intestinal toxaemia in convulsive seizures, and in various conditions of functional psychoses of which *dementia praecox* is a prominent example.

Chronic *sepsis* and chronic *septic foci* must be looked for and suppressed at an early stage in all convulsive, manic, and depressed nervous states; and every medical man recognises intestinal toxaemia as by far the most common auto-intoxication in mental cases.

Drainage and diminution of the harmful flora of the intestinal canal are essentials in treatment; and with the non-toxic bactericide Dimol the mental specialist has now the advantage of assistance not formerly at his disposal.

The efficiency of Dimol in the treatment of *intestinal disabilities of bacterial origin* is conclusively told in the interesting clinical reports, which, together with a brochure dealing with the pathological significance of the intestinal toxaemias, will be sent to any medical man on application to the

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat."

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food	Reconstituted (1 part in 8 parts of water)
Fat	15.5	1.7
Proteins	20.0	2.2
Lactose	58.0	6.4
Mineral Matter	4.5	0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T. M. & Design).

In Original Boxes of 12 "Sterules."

Price **3/=**

Containing 1, 2, 3, 4, 5, 6 or 10 minims (0.05; 0.1, 0.2, 0.25, 0.3, 0.35 or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving Angina Pectoris, Spasmodic Asthma, Migraine, Post-Partum Hæmorrhage, Hæmoptysis, Sea Sickness, to ward off Epileptic Attacks, &c., and as an Antidote to Chloroform.

Largely employed in threatened Fainting and Collapse, and as a restorative after Gas in Dental Operations.

"In ANGINA PECTORIS the best remedy. An early recognition of excessive tension is an important step towards longevity. To lower blood pressure Amyl Nitrite has a more rapid action than any other drugs, and is useful in cutting short the paroxysms of pain. Nitroglycerin in divided doses keeps the tension low during the day. Nitro-Erythrol has a lower and perhaps more prolonged action."—L., ii./05, 325; ii./06, 1335.

ANGINA PECTORIS GRAVIOR. The more pronounced attacks were treated with Amyl Nitrite and Nitroglycerin, which gave prompt relief.—B.M.J., ii./06, 304.

In all spasmodic affections, such as Angina pectoris, one of the best remedies.—B.M.J., i./09, 994.

Discussion on angina pectoris.—"The Nitrites are indispensable."—B.M.J., ii./09, 1122.

When the pain is acute Amyl Nitrite the quickest means of relieving.—L., ii./08, 1132.

Fear of death entirely disappeared as patient knew he could get relief from Amyl Nitrite or Nitroglycerin.—L., ii./09, 572.

In angina no drug can compare with Amyl Nitrite for immediate action and efficiency.—L., i./09, 240; L., ii./05, 812.

INTRATHORACIC ANEURISM. For the acute anginal attacks—Amyl Nitrite inhalation followed by internal use of Nitroglycerin or Erythrol Nitrate ¼ or ½ grain is generally efficacious.—L., i./13, 948.

In ASTHMA in most cases the reduction in blood pressure relieves.—B.M.J., ii./11, 1327.

POST-PARTUM HÆMORRHAGE immediately stopped; no further trouble followed.—B.M.J., ii./06, 1125.

HÆMOPTYSIS in pulmonary tuberculosis, 90 cases treated by immediate use of Amyl Nitrite, and with few exceptions promptly effective. Possession of the remedy secures peace of mind to sufferers.—L., i./08, 130.

Some convincing cases in which AMYL NITRITE SAVED LIFE.—L., i./07, 939.

In hæmoptysis, the general widespread vaso-dilation produced by Amyl Nitrite is preferable to the vaso-constriction effected by adrenaline internally.—L., ii./04, 1446.

In hæmoptysis Amyl Nitrite acts better the quicker it is used. In most cases it can be completely arrested if inhaled as soon as the first signs of blood show themselves in the sputum. If excitement afterwards of any kind, ¼ grain Morphine given. Amyl Nitrite, the drug *par excellence*, to be used first. Especially useful in sanatorium work where the patient is seen at the beginning of attack.

Hæmoptysis arrested in every case in which Amyl Nitrite was tried whether of mitral obstruction or from phthisis.—Edin. Med. J., July, 1904; L., ii./04, 522, 942, 1446; M.A., 1906, 240; B.M.J.E., i./06, 79. In severe hæmoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory.—B.M.J., i./06, 917.

In SEA-SICKNESS, inhalation from a "Sterule" is very useful; should be repeated every 2 or 3 hours if necessary.

In CHLOROFORM SYNCOPE Amyl Nitrite affords the quickest means of restoring the heart's action.

Infantile Convulsions well treated by 1 minim capsules.

Please specify MARTINDALE'S Amyl Nitrite "Sterules"—the Original Manufacturer.

We also Supply:

MANNITOL NITRATE TABLETS, 1 gr., 24, 3/6; 48, 5/6.
ERYTHROL NITRATE TABLETS, ½ gr., 24, 4/6; 48, 7/6.
(1, ¼ and ⅛ gr. also made, prices pro rata.)

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

MESSRS. KAYLENE, LTD.

April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

An Address
ON
THE NATIONAL INQUIRY INTO THE CAUSES OF OUR HIGH MATERNAL MORTALITY RATE.*

BY

T. WATTS EDEN, M.D.,

CONSULTING OBSTETRIC PHYSICIAN TO CHARING CROSS HOSPITAL.

WHEN the decision of the Ministry of Health to set up a National Committee to investigate the causes of maternal deaths in England and Wales was announced I was one of those who were inclined to think that, except in one direction, no very definite results could be anticipated from such an inquiry. It was clear that an inquiry conducted by the medical officers of health in the districts for which they were responsible might result in improved organization and in a better understanding on the part of doctors and midwives of the assistance which the public health authorities were able and willing to render in such ways as dealing with cases of difficult labour, or with cases in which septic and other complications developed after delivery, or in rendering assistance in the provision of extra food or medicines, or domestic help, to the poorer classes of their patients, or in placing laboratory investigation within the reach of these patients when conditions arose which called for such investigation. The great questions underlying the causation of maternal mortality, such as (*a*) the conditions which determine the occurrence of puerperal infection, (*b*) the causation of the toxaemias and the haemorrhages of pregnancy, (*c*) the steps required to provide better and longer practical training in midwifery both for medical students and for midwives—these questions could, it appeared, hardly be reached at all, certainly not closely investigated, by this inquiry. And until these three great questions, which lie at the heart of the problem, are seriously grappled with we can hardly expect to make any deep impression upon the figures of maternal mortality which have for so many years caused us, as doctors, the greatest concern, and which have now roused the conscience of the nation itself.

The inquiry set up by the Ministry is now fairly launched, and is, I believe, proceeding smoothly; but it is as yet too early to glean any indications as to the results which may emerge from it. We shall probably have to wait some time for these.

THE ABERDEEN INQUIRY.

It so happens, however, that a large Scottish city, Aberdeen, a town of some 160,000 inhabitants, has anticipated the Ministry of Health, and a similar inquiry has been proceeding there for the last ten years. The objects of the Aberdeen inquiry are identical with those envisaged by our own Ministry of Health, which, it will be remembered, has no jurisdiction in Scotland. The Aberdeen inquiry was conceived and organized by the then medical officer of health for the city—Professor Matthew Hay—who was also professor of medical jurisprudence in the University of Aberdeen when the inquiry was launched in 1917. The first report was published by the Scottish Board of Health in November, 1928, and is written by Dr. Parlane Kinloch, Dr. F. Smith, and Dr. J. G. Stephen. The information contained in this report is of great importance and interest, and it appears to foreshadow the kind of information which will be gained from the much more extensive inquiry now proceeding in England and Wales. I thought, therefore, that it might be of interest if we went over this report, with the object of gleaning from it such facts, or such conclusions, as may appear to bear a practical value.

The first step taken in the Aberdeen inquiry was to issue special regulations requiring the registrars of births, marriages, and deaths to make an immediate return to the Public Health Department of all maternal deaths occurring within a month (this period was later extended) of confinement, whether the death had been attributed to the confinement or not. This the registrar could do by checking the notified or registered births by the certified deaths of mothers. Occasionally an omission by the registrar was detected by means of information brought to the public health department by the district visitors. The authors of the report believed that such precautions as these were required in order that all cases which properly came within the scope of the inquiry might be disclosed. This view proved, in the event, to be correct, for the methods employed resulted in the disclosure of a considerable number of maternal deaths which would otherwise have remained concealed; in fact, the cases thus disclosed added 15 per cent. to the total number of maternal deaths. This is a very disquieting revelation, and if comparable results should be obtained generally, we shall have to admit that we have underestimated our maternal mortality rate by a considerable figure, and that the problem is of even larger dimensions, and greater gravity, than we supposed.

There are no details in the report as to the nature of the cases which were not certified. It is to be supposed that the investigators satisfied themselves that they were all cases of death properly attributable to child-bearing, although not regarded as such by the individual medical attendants.

I have no information about what is being done in the direction indicated in connexion with the English inquiry, but it would appear to be a point that should not be overlooked. Perhaps we may hear whether Nottingham has taken any similar steps to avoid the escape of cases which ought to be included in the returns.

In Aberdeen the actual inquiries were conducted in much the same manner as, I gather, it is the intention of the Ministry that our own inquiries should be carried out. In the case of both doctor and midwife an inquiry card was first sent out, asking for information under three heads: (*a*) home conditions and pre-natal health; (*b*) previous obstetric history; (*c*) main facts of the confinement. In the case of deaths in the practice of a midwife each midwife was interrogated by a member of the Department of Public Health, and additional information was obtained, if required, through health visitors.

In the case of doctors, we are told that a personal interview was generally requested with the doctor by a member of the health staff, and that the fullest respect was always given to his opinion; it is added that the relations between the doctors and the Health Department have been perfectly friendly in all cases. The medical officer of health often found that he could give useful information to doctors about the facilities which were available for obtaining assistance in necessitous cases, and about other matters. One can readily believe that this would be the case, for it was one of the directions in which it appeared that useful results could be confidently anticipated from an inquiry.

It is emphasized that the inquiries made were *private* inquiries, that no information obtained by the means described was, or would be, made public, and that in the publication of results the greatest care was taken to avoid the escape of any information received in confidence from doctors and midwives. We know that it is the expressed intention of the Ministry that the English inquiry should be conducted in the same scrupulously confidential manner, and that its objective is not to impute blame, but to discover upon what lines preventive work may best proceed.

The report, in fact, contains an interesting item of internal evidence that the relations between medical officers of health and practising doctors in Aberdeen have improved considerably during the period of the inquiry. This is shown by figures which are given as to the notification of cases of puerperal fever. It is well recognized that, over the country generally, only a small proportion of all cases of puerperal fever are actually notified as such; the temptation to call them something else is no doubt difficult to resist, and, further, diagnosis is not always an easy matter. The Aberdeen records show that until quite recently in that city practically only the cases which terminated fatally were notified, as is shown by the fact that the number of deaths roughly equalled the number

* Delivered to the Nottingham Medico-Chirurgical Society, March 27th, 1929.

of cases notified. In one quinquennium (1898–1902) the number of certified deaths actually exceeded the number of cases notified. In England and Wales non-certification of cases of puerperal fever has been quite as common as in Aberdeen. During the period of the inquiry there has been a very remarkable change in the attitude of Aberdeen doctors towards notification, and during the quinquennium 1923–27 the number of cases notified was nearly three times as great as the number of certified deaths. If this change is the result of closer contact between the practising doctors and the public health service then it speaks volumes both for the helpfulness of the medical officers of health and for the willing co-operation of the doctors. I regard this as one of the most promising features of the report.

FACTORS INFLUENCING MATERNAL MORTALITY.

We may now consider some of the results of the Aberdeen inquiry into certain factors which may be thought to influence maternal mortality.

First of all, a word as to the effects of *illegitimacy*. The illegitimate birth rate is relatively high in Aberdeen, and the number of cases under consideration is considerable, amounting to one-tenth of the total births during the ten years under consideration (3,331 out of a total of 34,653). The maternal death rate of the unmarried mothers is more than double the total rate, and the mortality from sepsis is three times as high as the total maternal death rate from sepsis. The problem of the care of unmarried mothers is as much a social as a medical problem, and it seems to me that this is a channel into which philanthropic effort might well be guided, for there is surely much to be done, much which cries loudly to be done, in helping these heavily burdened women through the ordeal which is to them infinitely more formidable than it is to their married sisters.

The influence of the *general health* of the mother upon maternal mortality is a question upon which very little information has hitherto been available. The Aberdeen report does not overlook this matter, but it is naturally a difficult subject for investigation. For the purposes of their inquiry "general health" was divided into two classes—"good" and "unsatisfactory." We have, of course, no information as to the proportion of the total adult female population of Aberdeen which suffers from "unsatisfactory" general health, but the investigators found that among the women who died from causes associated with child-bearing 31.8 per cent. (roughly one-third) had been in unsatisfactory general health *before the beginning* of the pregnancy which terminated fatally. This must be much in excess of the general rate of unsatisfactory health among the total adult female population.

With regard to the health of the mother *during* pregnancy, the Aberdeen records from the ante-natal departments show that, generally speaking, 80 per cent. of expectant mothers are classed as being in "good" health. Among those who died in the period covered by the inquiry only 40 per cent. were classed as having "good" health.

I am not suggesting that these findings should be accepted without confirmation, but they certainly seem to imply that more careful attention to the general health of our prospective mothers is a direction in which useful preventive work may be done. Dr. Charles Douglas of Cupar has for several years been preaching the importance of the maternal factor in determining the risks of child-bearing, and this piece of evidence, as far as it goes, justifies his attitude, for it suggests that the expectant mother who is in poor health runs a considerably greater risk than one whose health is good.

There are certain points with regard to which the report confirms what may be termed conventional views—for example, that the risks of the first confinement are the greatest, that housing conditions, such as overcrowding and defective cleanliness, and what might be called stringency of means, have no apparent influence in increasing the risks of childbirth. The advantages of *ante-natal supervision* are confirmed in the statement that the death rate among those who attended ante-natal clinics was approximately only one-half of the rate among those who did not—3.8 to 7.3 per cent. respectively.

When the report comes to deal with the *venue of the confinement*, the results which emerge are startling: 3,765 confinements (roughly 10 per cent. of the total) took place in institutions, under which term are included hospitals and nursing homes; of these, roughly one-third were cases specially admitted either because of ante-natal complications or from difficulties encountered during the course of labour; the remainder, roughly two-thirds (2,220), were cases for which the institutions had been responsible throughout. It is instructive to compare the results obtained by the institutions in the cases for which they were solely responsible with those obtained privately by practising doctors and midwives. The total maternal death rate for the city from all causes over the ten years was 6.6 per thousand, a figure rather higher than the average for England and Wales. The maternal death rate for the 2,220 cases for which the institutions were directly responsible reached the astonishing figure of 14.9 per thousand; the corresponding rate for patients attended in the hospital districts was 5.6 per thousand, that for patients attended privately by doctors was 6.9 per thousand, and that for cases attended by midwives only—that is, without medical assistance—was 2.8 per thousand; for cases attended by midwives, with medical assistance, the rate was the lowest of all—namely, 2.5 per thousand. The death rate from sepsis was also remarkably high in the cases delivered in institutions, and for which the institutions were solely responsible. The general mortality rate for sepsis in Aberdeen during the period of the inquiry was 1.5 per thousand—about the average for the whole country; in the institutional cases it reached 4.5 per thousand; in the remaining groups just specified it was below the average, attaining the lowest point of all in the cases attended in the hospital districts, for which the rate was only 0.7 per thousand—that is, less than one-half of the general septic rate. The report does not distinguish the results obtained in private nursing homes from those in other institutions.

One cannot help regarding these returns with great disquietude. The old prejudice among mothers in favour of having their babies at home is disappearing, and they are becoming more and more willing, indeed often anxious, to go into an institution instead. We have been urging mothers to do this in the expectation that they would receive better care, and would in consequence be freer from risks in these institutions than at home. In this belief the Ministry of Health has encouraged municipalities to open maternity homes available for all to whom the arrangements for a confinement involve a difficult financial strain. We knew already that the results obtained in these municipal homes were not entirely satisfactory, but the results disclosed in Aberdeen are more than serious, unless there be some special explanation of them which does not appear in the report. A partial explanation of the relatively high maternal death rate in institutions may possibly be found in the more difficult or complex character of the cases dealt with by these institutions, but in compiling the figures I have just given you all *emergency* cases have been eliminated—that is, those transferred to the institution after previous treatment by doctors and midwives. The figures, therefore, apply only to cases for which the institutions had been responsible throughout. Thus the institutional death rate from albuminuria and convulsions is more than two and a half times as high as the general rate for that condition for the city (no emergency cases being included), the rates being 2.7 and 1.0 per thousand respectively. Also the death rate from haemorrhage is more than double the general rate for that condition (1.4 and 0.7 per thousand). The report does not distinguish between ante-partum and post-partum haemorrhage, so that the obstetric significance of the latter figures is not very clear.

We see, then, that the death rate from sepsis in the institutions was exactly three times as high as the death rate for the whole city from that condition (4.5 and 1.5 per thousand); and for this distressing fact no explanatory circumstances are forthcoming in the report.

So far as we have gone the instructive results emerging from this report are: first, the evidence suggesting that the general health, and perhaps also the physique, of the mother have more influence upon maternal mortality than

we have hitherto believed; and secondly, the relatively high mortality from all causes occurring among women whose confinement had been managed throughout in the in-patient departments of hospitals and other institutions.

ETIOLOGY OF PUERPERAL SEPSIS.

A considerable body of work is presented in the report dealing with the causation of puerperal infection. The bacteriological work confirms the view, now almost universally held, that a haemolytic streptococcus is the causative organism in all but a small minority of cases. The question of how this organism gains access to the maternal passages is reviewed. The possibility that streptococci may make their habitat in the cervical and vaginal secretions during pregnancy, and after labour may become active and invade lacerations or the placental site, while admitted, is dismissed as being possible in only a very small proportion of cases. We are told that the natural habitat of the haemolytic streptococcus is the throat. Great importance is attached to the possibility of "droplet infection"—that is, infection of hands, instruments, or appliances by droplets of saliva expelled, in speaking or coughing, from the mouth of a carrier of the haemolytic streptococcus. In support of this view it is mentioned that in January, 1928, an outbreak of puerperal fever occurred in a maternity institution in Aberdeen in which 12 cases became infected, of whom 4 died. The outbreak was found to be due to the haemolytic streptococcus; an outbreak of icterus neonatorum accompanied it, which proved fatal in 7 cases, and in 2 of the fatal cases the haemolytic streptococcus was proved to be the cause of the infants' death from septicaemia. Throat cultures were taken from the twelve nurses in the institution, and in five of them the haemolytic streptococcus was found. Seventeen contacts among patients were also examined, with the result that in eight of them haemolytic streptococci were found in either the throat or the uterus, or in both—that is, eight out of seventeen examined were found to be carriers.

In pursuance of this view it is suggested that many individual doctors and midwives may unconsciously be carriers of the causative organism of puerperal sepsis, and may convey infection to their patients by what is known as the "droplet" method. In support of this the report points out that in Aberdeen, during the period of the inquiry, the death rate from sepsis among women attended privately by doctors was nearly double the rate found in women who had been delivered by midwives, either alone or with medical assistance. Doctors being brought more frequently into contact with other diseases of streptococcal origin, such as scarlet fever, erysipelas, and pyogenic conditions, are more likely, it is suggested, to become carriers of the organism than are midwives, who are relatively immune from risks of contact with these conditions.

It is not necessary for us at this stage to do more than pigeon-hole this theory for future consideration. The medical officer to the Scottish Board of Health (Dr. T. F. Dewar), in a preface to the Aberdeen report, very fairly points out some of the difficulties in accepting the theory of throat infection as the usual channel by which the infecting organisms reach the maternal passages. In the course of the extensive English inquiry now in progress no doubt other theories will be advanced, and it is all to the good that we should be in a position to consider all the possible explanations which research and discussion may bring to light. On the other hand, the theory of throat infection cannot be lightly dismissed. It certainly offers a possible explanation of those rare but puzzling cases of sepsis which occur in patients, who can be proved not to be carriers of streptococci themselves in the cervical or vaginal secretions, and who have been confined in hospitals of repute. If the theory of throat infection as the usual channel were to become established, one feels appalled at the prospect of the consequences which would ensue in the practical work of midwifery. The task of discovering carriers, their suspension from work until freed from the organism, the means which might have to be employed to free them, and the practical impossibility of preventing droplet distribution by any form of mask worn by the medical and nursing attendants, suggest only a few of the complications which the establishment of the theory would entail. Let us hope that further work may relegate it to a position of rarity among the possible channels of infection.

In considering puerperal sepsis we must, however, face the fact that in institutions this disease still assumes epidemic form; it is true that the outbreaks are not comparable in extent or in severity to those which devastated lying-in hospitals so frequently in pre-antiseptic days. It has to be admitted, however, that we have not got rid of epidemics of puerperal fever in our lying-in institutions, and it appears to me that this is one of the most serious features of the problem of maternal mortality. I have mentioned the outbreak which occurred in an Aberdeen hospital in January, 1928. We are told in the report that "Similar outbreaks of puerperal sepsis, spread by gross contagion, occurred in 1922 and in 1924." The report does not state the total number of deaths for which the two earlier outbreaks were responsible; we know, however, that in the third epidemic 4 died, and the total number of deaths from sepsis in the institution during the ten years of the inquiry was only 10. It is therefore probable that the three epidemics in 1922, 1924, and 1928 accounted for the great majority, possibly for all, of the institutional deaths from sepsis. If these outbreaks could have been prevented a notable reduction of the maternal mortality rate from sepsis in Aberdeen would have resulted.

A good deal of information is available which shows that similar outbreaks have occurred in other centres than Aberdeen, so that the conditions which favour the occurrence of such outbreaks are not peculiar to that city. Through the kindness of Dr. Parlane Kinloch I have been furnished with details of an outbreak which occurred a few months ago in an English town. In this town there is a small maternity hospital of fourteen beds, staffed by a matron, nurses, and pupil midwives. In December, 1928, an outbreak of puerperal fever occurred in this hospital, in which three women only were affected, and all three died. The throats of all the staff were examined and haemolytic streptococci were found in the case of the matron and several others. The epidemic was controlled by closing the hospital entirely for disinfection, and sending the staff away for a few days' holiday.

In connexion with this hospital a certain small number of women are attended in their homes by a midwife assisted by pupils. The midwife who attends the district cases has no duties in the hospital itself. In January, 1929, three cases of puerperal fever occurred in women attended in their homes by this midwife and a pupil, and again all of them proved fatal. It is known that the midwife's throat was free from the haemolytic streptococcus at the time of the outbreak in the hospital, but unfortunately neither the district midwife nor her pupil was re-examined when the cases occurred in the district. The pupil was one of those whose throat culture gave positive results at the time of the hospital outbreak, and further inquiry showed that this particular pupil had been in actual attendance on the three women who died during the first epidemic. The presence of this pupil seemed to be the only factor common to all six of the cases. The hospital accordingly dispensed with her services, and she decided to give up the idea of qualifying as a midwife. Wherever the infecting organism may have come from, it was evidently one of high virulence, the case mortality of the two outbreaks being 100 per cent.

The evidence so far adduced in support of the theory of throat infection cannot be regarded as conclusive. Probably haemolytic streptococci could be found in the throats of the majority of healthy persons, and proof requires something further than their discovery in the throat of an attendant at the confinement. Assuming that they can be conveyed by "droplet" infection to the parturient canal, is it certain that these throat organisms are capable of setting up an acute blood infection? Or is it possible that in some instances they are capable of so doing, and in other instances they are not? In the latter case, is it practicable to distinguish between throat cultures which are dangerous and those which are not? Assuming that the majority of healthy persons are throat carriers of the haemolytic streptococcus, and that this organism can be borne by droplet infection to the genital canal, would not puerperal infection be very much commoner than it actually

is? One would like to see the theory supplemented by exact experimental observations before accepting it.

If a single case of acute infection occurs in a hospital or other institution, the evidence is conclusive that it is liable to spread by gross contagion from one woman to another, and also to the infants. It is clear that the ordinary methods of isolation and of disinfection, and perhaps also the routine antiseptic technique, of these institutions in which outbreaks have occurred, are not adequate to prevent the occasional occurrence of puerperal infection within their walls, and given the occurrence of a single case they are unable adequately to protect their other patients from the risks of contagion. Now that the English inquiry is fairly launched, any further outbreak which occurs will no doubt be studied as an epidemic phenomenon by the experts of the local health departments.

In its bacteriological aspects the Aberdeen outbreak of 1928 was very closely studied, and the suggestions I have referred to as to throat infection were the direct outcome of this work. No information is given, however, apart from this, about the conditions which permitted the infection to be conveyed from one patient to another in the hospital, or as to how these conditions could be remedied.

Isolation of Septic Cases.

It would appear that the provision of adequate facilities, whether public or private, for the isolation of all septic cases must be regarded as essential; and isolation must be effected immediately, as in the case of all other notifiable infectious fevers, for every day's delay multiplies the risks. In fact, an isolation block is a *sine qua non* of a properly equipped maternity hospital, for the experience I have referred to shows that the less complete methods of segregation which are now employed cannot be relied upon. The isolation block would require its separate building, its separate staff, its separate operating theatre and equipment, and would consequently be very expensive to provide. The numerous small maternity hospitals which now exist, and which have increased so rapidly in recent years owing to the policy of the Ministry of Health in encouraging the provision of municipal maternity homes, have been organized on the simplest lines in order that they may come within the reach of the middle classes, and they have as a rule no effective means of isolating septic cases. The consequence is that there have been a number of outbreaks of puerperal sepsis in them. The difficulties of these small institutions are increased by the fact that when a septic case occurs there is so much difficulty in getting it transferred to another place, although the Poor Law hospitals, and in London the fever hospitals of the Metropolitan Asylums Board, are able and willing to undertake the care of these cases, but patients are not willing to be sent to these hospitals.

The provision of isolation blocks in connexion with all our great maternity hospitals, to which both private cases and others from small institutions could be immediately transferred, would permit of an intensive study of puerperal sepsis by a combined team of obstetricians, bacteriologists, and public health authorities, which up to now has never been carried out on a sufficiently large scale. It may be a long time before we can attain such a system as this, but I am glad to know that an institution to which I have been attached for many years, Queen Charlotte's Hospital in London, has made the erection of an isolation block the first step to be taken in the projected building of the new hospital, which is to take the place of the old one.

Doctors' Cases and Midwives' Cases.

There is one more matter in the Aberdeen report to which I must draw attention. The report has been able to differentiate between the cases attended by doctors and those attended by midwives, and emphasis is laid on a comparison of the results. It appears from this comparison that the doctors' cases showed a general maternal mortality rate of 6.9 per thousand, and the midwives' cases a rate of only 2.8 per thousand. Attention has been called by Dame Janet Campbell, in the Ministry of Health reports, to the fact that the returns of midwives' cases in many localities show a death rate well below the average maternal death rate; and Dr. Fairbairn has shown that the picked body of midwives who work for the Queen Victoria's Jubilee Institute for Nurses have achieved even better results than those disclosed by the Ministry of Health, and that their results are progressively improving. The Aberdeen report is, however, I believe, the first report in which it has been possible to institute a direct comparison between cases attended privately by doctors and those attended by midwives. I know that the comparison between doctors' and midwives' cases is to some extent an unfair one, because midwives accept none but normal cases, or cases which they believe to be normal; while doctors get a correspondingly large number of abnormal, and therefore more difficult ones.

Now I mention this matter not with the idea of imputing blame or suggesting explanations, but because by the Aberdeen report it is made the basis of a plea for a fresh orientation of midwifery practice, or, in the words of the report, "a new midwifery organization in which midwives conduct all normal deliveries, and in which doctors provide the ante-natal services and deal with obstetrical complications." This, they believe, would result in "a significant reduction in maternal mortality." I have already mentioned that the report attributes greater risks to doctors than to midwives of becoming throat carriers of the streptococcus, and this consideration has no doubt weighed heavily with the authors in making this proposal.

Now I should very much like to know what my colleagues in general practice will think of this proposal. So far as I can judge at present the definite objections to it appear to me to outweigh the more or less problematical advantages. There is a basic objection which I think is of great importance—namely, that the ability of doctors generally to deal with cases of obstetrical complications will steadily deteriorate if experience in normal midwifery is withdrawn from them. An intimate acquaintance with the course of the birth process under normal conditions is the first requisite for dealing with complications, and do we not all know that intimate knowledge can only be acquired, and when acquired can only be maintained, by constant practice? I have always held that it was the duty of an obstetric specialist to maintain touch with normal labour, by undertaking the private care of a certain number of cases each year, as well as by his hospital work. And what is true of the specialist will equally apply to the doctors who, under this new scheme, would be required to deal with the complicated cases. The tendency would be that the work of dealing with these cases would pass into the hands of a few men in each locality, while the remainder of the practising doctors withdrew from midwifery altogether. This, to my mind, would be a deplorable result. Midwifery has long been regarded as an essential subject in the examination for registration as a medical practitioner, and has taken its place alongside medicine and surgery in the foundations of medical education. To withdraw it from the sphere of the general medical practitioner would be to change its status as a basic subject in medical education, and would deprive the practitioner of work which he can undoubtedly be trained to do with success and with advantage to the community.

I think it can be anticipated that other reports will in time appear dealing with the same point—that is, in the way of comparison between doctors' and midwives' cases. It may be that they will not correspond with the data given us from Aberdeen, but if the contrary should be the case—I mean if similar results should appear generally—the medical profession will be brought face to face with a situation so grave that it cannot be ignored. This matter cannot be dealt with in a few words, but I feel that we should all be thinking about it, about its many implications and the consequences which would inevitably follow if this situation persists and is shown to apply generally. It would indeed constitute a serious indictment of our profession if the opinion became established that partly trained women were more successful in the management of normal midwifery than are fully trained members of our profession.

I hope what I have said about the Aberdeen report will show that, although it adds little to our knowledge of the causes of maternal mortality, it is yet of great interest and does a great deal to indicate the direction along which further inquiries may usefully proceed. We do not know what are the intentions of the Ministry of Health with regard to the English report; we may get a series of reports from different centres, or we may have to await the preparation of a national report. The work will occupy many years, and I am sure we shall be prepared to do everything we can to assist the investigators in their tremendous task, realizing how urgently necessary it is in the national interest to reduce our terrible wastage of maternal life.

A Study
OF
THE BACTERICIDAL POWER OF THE BLOOD DURING PREGNANCY AND THE PUERPERIUM,
*AND ITS RELATIONSHIP TO THE DEVELOPMENT AND COURSE OF PUERPERAL INFECTION.**

BY

DOUGLAS MILLER, M.D., F.R.C.S.ED.,
PHYSICIAN, EDINBURGH ROYAL MATERNITY HOSPITAL; ASSISTANT GYNAECOLOGIST, EDINBURGH ROYAL INFIRMARY;

AND

J. R. WHITAKER, JUN., M.B., B.S.LOND.,
FORMERLY UNIVERSITY ASSISTANT, DEPARTMENT OF BACTERIOLOGY, EDINBURGH UNIVERSITY.

(From the Departments of Midwifery and Bacteriology, Edinburgh University.)

THE introduction of pyogenic organisms into the reproductive tract, with or without trauma as an important contributory agency, is recognized as the commonest and most important factor in the causation of puerperal infection. While this is so, the anomalous nature of its incidence is a commonplace attribute of this disease; the occasional appearance of infection in a case in which delivery has been spontaneous and even free from examination, and on the other hand its failure to develop where trauma and manipulation have made its occurrence probable, constitute a paradox with which everyone engaged in midwifery practice is familiar.

A partial explanation of this phenomenon was suggested by those workers who investigated the cervical and vaginal flora during pregnancy and attempted to relate the occasional unexpected development of sepsis to a pre-existing infective condition of the genital passages. The recent observations of Burt-White and Armstrong,[1] however, would appear to call into question the validity of the conclusions offered by previous observers. Burt-White and Armstrong examined the cervical flora in 55 pregnant women; in 40 per cent. of these cases streptococci of different types were isolated, but in only one did the strain present the characters of the *Streptococcus pyogenes*, the common cause of puerperal fever; they report, moreover, 15 cases of pregnant women whose cervices harboured haemolytic streptococci, including *Streptococcus pyogenes*, and in none did sepsis occur. These workers conclude that "the presence of the haemolytic streptococcus in the reproductive tract does not necessarily give rise to sepsis in the puerperium," and state further that their results appear "to support definitely an exogenous origin for infection in puerperal sepsis, while leaving unexplained those rare cases of sepsis in which there has been no manipulation during pregnancy or labour." A similar conclusion is suggested by a study of the epidemics of puerperal sepsis with which hospitals in pre-Listerian days were ravaged, and Young[2] instances in this connexion the long intervals of freedom from fatal sepsis in support of the view that, as compared with trauma and contagion, autogenous infection must at best play a minor part in the etiology of the disease.

Bacteriological and clinical evidence seems accordingly to warrant the inference that puerperal sepsis can rarely be explained on the basis of an endogenous infection. It appeared to us possible, however, that the occurrence of sepsis in cases in which there has been a minimum of interference might be related to an abnormally low degree of resistance on the part of the individual; a variation in susceptibility of this nature would readily explain the capricious distribution of puerperal sepsis—for example, in the lying-in wards of a maternity hospital.

To test the validity of this hypothesis it was decided to examine the bactericidal and bacteriostatic* power of the blood in a large series of pregnant and parturient women. Coincidentally with this larger investigation the skin sensitiveness to streptococcal toxin was examined in a small number of those women in whom at the same time the bactericidal power of the blood was tested. The toxin employed in the test of skin sensitiveness was isolated from a culture of a haemolytic streptococcus found in the blood of a woman suffering from puerperal sepsis and was prepared by the method described by Lash and Kaplan.[3]

For two reasons it was decided not to persevere with the examination of skin sensitiveness as a method of determining individual susceptibility to infection. In the first place, in those cases in which this reaction was tested no relationship was observed between the type of reaction and the incidence of pyrexia in the puerperium. Of the 49 women tested, 10 were toxin-sensitive, while 39 did not react; among the positive reactors the puerperium was morbid in two cases, in one of which delivery was effected by forceps; of the non-reactors six women, one of whom was delivered by forceps, experienced morbid puerperia. The inconsistent character of these results is disappointing in view of the observations of Burt-White,[4] who found a morbidity rate of 30 per cent. in women who reacted positively to streptococcal toxin. It should be mentioned, however, that Burt-White employed scarlatina toxin and that his investigation was on a scale considerably larger than that here reported. In those cases in which the two tests above referred to were carried out it was found that one had no relationship to the other, the bactericidal power of the blood being in point of fact higher as a rule in those cases in which the skin reaction was positive than in those in which it was negative.

In the second place, although a negative skin reaction of the type referred to may indicate that the patient possesses antitoxic substances to streptococcal toxin, it is probably not in the same sense a measure of resistance on the part of the individual to the important *locally invasive* as distinct from the *toxin-producing* property of the organism, a property which, from anatomical considerations, is of special importance in puerperal sepsis. In the expectation that such resistance to organismal invasion might possibly be related to the bactericidal activity of the blood, we decided to employ this test in our investigation, and were influenced further in our choice by its non-specific character (see Table II), and its applicability, therefore, to forms of infection other than streptococcal.

The method employed in the examination of bactericidal and bacteriostatic power was that described by Wright, Colebrook, and Storer,[5] and consists essentially in mixing whole blood with a known quantity of bacteria on "slide cells," the bactericidal power being gauged by the number of colonies which develop after incubation for twenty-four hours.

One disadvantage of this method may be mentioned: in an investigation of this kind a very large number of individual observations is required to provide the necessary data. This is so in the first place because of the technical impossibility of preparing for the purposes of a series of tests, carried out at different times, inocula each of exactly the same uniform density, with the result that a direct comparison is possible only between units of a group each member of which has been tested with the same inoculum, and not between units of different groups in

* Read at a joint meeting of the Edinburgh Pathological Club and Edinburgh Obstetrical Society, April 17th, 1929.

* The term "bacterio-static" implies inhibition of bacterial growth. Wright[5] has interpreted the results obtained by the method which he originally described as due to a "bactericidal" action; it seems possible that growth inhibition may also be an important factor, but while recognizing this we have in this paper employed the term "bactericidal," as originally used by Wright.

which different inocula may have been employed.[6] Furthermore, as the subjoined table shows, after blood has been drawn off it loses, at first slowly, then more rapidly, its bactericidal property.

Blood was withdrawn from the same individual at the same time each day on four successive days; on the fourth day all the samples were tested together, approximately 80 organisms being implanted in each sample.

TABLE I.

The number of colonies which grew in—	
Blood tested as soon as withdrawn	= 5
Blood kept for one day	= 18
Blood kept for two days	= 38
Blood kept for three days	= 63

Because of this deterioration in the bactericidal power of the blood on keeping it is possible only to compare the results in a group of samples of blood withdrawn at approximately the same time. Each group has to be investigated at once and considered individually. In practice it was found convenient to examine at one time a group of six samples of blood all withdrawn simultaneously and all tested with one inoculum of uniform density.

Before presenting the results of our investigation two further preliminary observations may be made: (1) Little or no variation has been observed in the bactericidal power of the blood of a healthy individual from hour to hour, or from day to day; this finding is not in keeping with the observation of Alston[7] that a diurnal variation in bactericidal activity occurs. (2) In the majority of our observations a twenty-four-hour broth culture of *Staphylococcus aureus*, dilution 1 in 5,000, was employed; the non-specific character of the test, however, is illustrated in Table II.

TABLE II.

Patient	Twenty-four-hours broth culture Staph. aureus, dilution 1 in 5,000: viable organisms introduced estimated to be 85.					Streptococcus (haemolytic type), dilution 1 in 5,000: viable organisms introduced estimated to be 176.				
	Slide Cells.				Average No. of Colonies.	Slide Cells				Average No. of Colonies.
	(1)	(2)	(3)	(4)		(1)	(2)	(3)	(4)	
1	18	17	16	13	16	50	42	35	32	35
2	25	24	20	26	24	63	64	65	67	61
3	25	30	21	24	25	47	70	53	65	59
4	34	25	34	34	32	74	87	61	63	72

In all, the bactericidal power of the blood of 396 individuals was examined; as each sample of blood was incubated with organisms in four separate "slide cells," and each of these four subdivisions individually examined, a total of approximately 1,600 clinical experiments was performed.

The first series of experiments was undertaken to determine whether or not such individual variation in bactericidal activity as might exist could be related to the incidence of pyrexia in the puerperium. This series comprised 229 healthy individuals, all of whom experienced spontaneous, uncomplicated labours, blood being withdrawn at or about the time of delivery. There were in this group 17 women who subsequently experienced febrile puerperia due to pelvic infection. *An analysis of these cases shows that in 14 of them the degree of bactericidal power in the patient who subsequently developed sepsis was lower than the average bactericidal power of the other members of the respective groups, while in 3 cases it was higher.* These findings appear to us of such importance that we include a short summary of the cases herewith.

Brief Notes of 17 Women who, subsequent to Delivery, Experienced Morbid Puerperia.

Case 39.—Spontaneous delivery; mild sepsis; one vaginal examination; blood withdrawn 5 hours after delivery; colonies = 82; average number of colonies in group = 54.

Case 14.—Spontaneous delivery; severe sepsis; blood withdrawn 6 hours before delivery; colonies = 90; average number of colonies in group = 55.

Case 3.—Spontaneous delivery; mild sepsis; blood withdrawn 24 hours after delivery; colonies = 22; average number of colonies per group = 17.

Case 27.—Spontaneous delivery, mild sepsis, blood withdrawn one hour after delivery; colonies = 2; average number of colonies in group = 6.

Case 54.—Spontaneous delivery; one vaginal examination; severe sepsis; blood withdrawn 6 hours before delivery; colonies = 21; average number of colonies in group = 6.

Case 59.—Spontaneous delivery; one vaginal examination; mild sepsis; blood withdrawn 6 hours before delivery; colonies = 59; average = 21.

Case 93.—Spontaneous delivery; one vaginal examination, died from acute streptococcal septicaemia 7 days after delivery; blood withdrawn 10 hours after delivery; colonies = 60; average = 19.

Case 175.—Spontaneous delivery; mild sepsis; blood withdrawn 7 days before labour; colonies = 12; average = 5.

Case 145.—Spontaneous delivery; two vaginal examinations; mild sepsis; blood withdrawn one hour after delivery; colonies = 3; average = 6.

Case 129.—Spontaneous delivery; one vaginal examination; mild sepsis; blood withdrawn one hour before delivery; colonies = 12; average = 5.

Case 121.—Spontaneous delivery; one vaginal examination; mild sepsis; blood withdrawn at onset of labour; colonies = 7; average = 3.

Case 169.—Spontaneous delivery; one vaginal examination; died of acute streptococcal septicaemia; blood withdrawn 20 hours after delivery; colonies = 10; average = 17.

Case 224.—Spontaneous delivery; no vaginal examination; mild sepsis; blood withdrawn 10 hours after delivery; colonies = 21; average = 17.

Case 103.—Spontaneous delivery; three vaginal examinations; severe sepsis; blood withdrawn 5 days before labour; colonies = 52; average = 37.

Case 37.—Spontaneous delivery; four vaginal examinations; mild sepsis; blood withdrawn one week before labour; colonies = 113; average = 70.

Case 102.—Spontaneous delivery; three vaginal examinations; severe sepsis; blood withdrawn at onset of labour; colonies = 14; average = 5.

Case 218.—Spontaneous delivery; three vaginal examinations; mild sepsis; blood withdrawn 12 hours after delivery; colonies = 70; average = 45.

A further investigation, complementary to that just described, was concerned with cases in which labour had been seriously complicated and in which, from the amount of interference and extent of trauma, it appeared probable that serious sepsis would develop. Twelve such cases were investigated, each potentially septic case being as far as practicable grouped along with women who had experienced normal labours, the latter constituting a control by which the degree of bactericidal power might be compared. In each of the twelve cases referred to the blood in one of the four "slide cells" was not inoculated, so that should the blood already contain organisms their presence might in this way be detected and a source of fallacy be excluded. In none of the twelve cases examined, however, was any organismal growth obtained in the "slide cells" which were left unimplanted as described.

In eight of the twelve groups investigated the bactericidal power of the potentially septic case was above the average of that of the other members of the respective groups; all of these patients recovered, and in two cases (*vide infra*, Cases 313 and 201) in which there had been extensive trauma and contamination the puerperium was afebrile. In one case no difference was noted in the degree of bactericidal power of the "suspect" as compared with the others; this patient recovered. In three cases the bactericidal power of the potentially septic patients was lower than the average; two of these patients died.

Short Notes on the 12 Cases referred to above.

Case 49.—Labour 60 hours; numerous vaginal examinations; difficult forceps delivery; mild sepsis; recovery; blood withdrawn 9 hours before delivery; colonies = 10; average = 30.

Case 215.—Labour 28 hours; numerous vaginal examinations; difficult forceps delivery; traumatic post-partum haemorrhage; primary cervical repair; mild sepsis; recovery; blood withdrawn 2 hours before delivery; colonies = 6; average = 35.

Case 94.—Labour 36 hours; numerous vaginal examinations; difficult forceps delivery; mild sepsis; recovery; blood withdrawn 12 hours after delivery; colonies = 8; average = 19.

Case 318.—Labour 28 hours; unsuccessful forceps outside; craniotomy; extensive laceration; severe sepsis; recovery; blood withdrawn 2 hours before delivery; colonies = 2; average = 13.

Case 326.—Labour 55 hours: numerous vaginal examinations; forceps delivery; mild sepsis; recovery; blood withdrawn 2 hours before delivery: colonies = 2; average = 13.

Case 311.—Labour 28 hours: unsuccessful forceps outside; forceps delivery; extensive laceration; normal puerperium; blood withdrawn 12 hours after delivery; colonies—no growth; average = 14.

Case 161.—Shoulder presentation; early rupture of membranes; labour 60 hours; ineffectual attempts to deliver outside; Caesarean hysterectomy; clinically very bad prognosis; cellulitis; recovery; blood withdrawn immediately before operation; colonies = 5; average = 16.

Case 261.—Labour 20 hours; unsuccessful forceps outside; spontaneous delivery in hospital; extensive laceration; normal puerperium; blood withdrawn 36 hours after delivery; colonies=33; average = 49.

Case 81.—Labour 40 hours; unsuccessful forceps outside; spontaneous delivery in hospital; normal puerperium; blood withdrawn 21 hours after delivery: colonies = 22; average = 22.

Case 21.—Labour 31 hours; unsuccessful forceps outside; forceps delivery; severe sepsis; recovery; blood withdrawn 18 hours after delivery: colonies = 16; average = 12.

Case 230.—Labour 14 hours; unsuccessful forceps outside; craniotomy; death from streptococcal septicaemia 14 days after delivery; blood withdrawn 60 hours after delivery; colonies = 32; average = 10.

Case 93.—Difficult forceps delivery outside; post-partum eclampsia; death from streptococcal septicaemia 4 days after delivery; blood withdrawn 30 hours after delivery; colonies = 32; average = 7.

There were in these two series of observations, comprising a total of 29 cases, 7 cases (Nos. 3 and 100 in the first series, and the last five cases in the second) in which blood was withdrawn for examination more than twelve hours after delivery; the findings in these cases must on that account be interpreted with caution as representing the primary degree of haemo-bactericidal power possessed by the individual. With these exceptions, however, the investigation was made either before delivery or so soon afterwards as probably to anticipate any serious modification in antibacterial activity which might result from the introduction of infection. The data obtained appear to show with considerable conclusiveness that the degree of resisting power to infection, as measured in this way, has an important influence on the subsequent development and course of puerperal sepsis.

The variation in degree of antibacterial power which the above investigation disclosed led naturally to an effort to determine the factors on which this variability might depend. The next series of experiments accordingly was undertaken to determine (1) whether or not the degree of bactericidal power varied as between pregnant and non-pregnant individuals; (2) whether the bactericidal power during pregnancy was within limits constant or was influenced by the stage of gestation reached; and (3) the influence on bactericidal power of multiparity as compared with nulliparity or primiparity, and of such conditions as albuminuria, prolonged labour, instrumental delivery, and severe blood loss.

I. A Comparison of the Bactericidal Power of the Blood in Pregnant and Non-pregnant Individuals* (see Chart 1).

A series of observations was made in which the blood of healthy non-pregnant individuals was compared with that of women at or about the sixth month of pregnancy, at the end of the eighth month of pregnancy, at the time of delivery, and at ten days, at six weeks, and at twelve weeks after delivery. The following results were obtained:

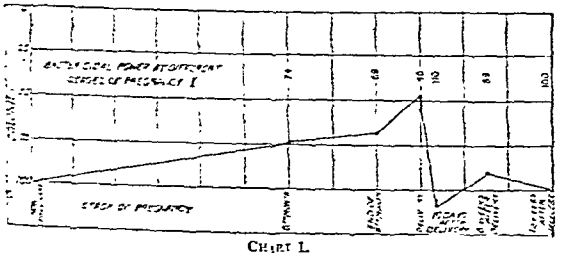

Chart I.

A. *Comparison of Non-pregnant Women and Women at or about the Sixth Month of Pregnancy.*—Three groups of cases were investigated, each containing three non-pregnant and three pregnant individuals. In each of the three groups the average bactericidal power of the pregnant exceeded that of the non-pregnant women. The combined ratio, pregnant to non-pregnant, expressed in terms of the colonies which formed after incubation, was approximately as 74 to 100. The method of calculation is shown in the following table.

Table III.

Case	Group I.		Group II.		Group III.	
		Average No. of Colonies.		Average No. of Colonies.		Average No. of Colonies.
1	Pregnant	8	33		27	
2	.. ..	6 } 6	28 } 32		17 } 23	
3	.. ..	5 }	30 }	= 60/100	25 }	= 82/100
4	Non-pregnant ...	7	32		13	
5	.. ..	10 } 10	50 } 40		31 } 23	
6	.. ..	14 }	38 }		35 }	

Combined group ratio, pregnant to non-pregnant ... ... = 60/100 + 80/100 + 82/100 = 74/100.

As the number of organisms introduced was not constant for each group this figure represents an approximate and qualitative rather than an exact mathematical ratio.

B. *Comparison of Non-pregnant Women and Women at End of the Eighth Month of Pregnancy.*—Six groups of cases were investigated, each group containing two or more non-pregnant and two or more pregnant individuals. In four groups the average bactericidal power of the pregnant exceeded that of the non-pregnant; in one group no difference was found, and in one group the bactericidal power of the non-pregnant women was the higher. The combined ratio, pregnant to non-pregnant, expressed in terms of colonies, was approximately as 69 to 100.

C. *Comparison of Non-pregnant Women and Women in Labour or Shortly after Delivery at Term.**—Seven groups of cases were investigated, each group containing two or more pregnant and two or more non-pregnant individuals. In six groups the average bactericidal power of the parturient individuals exceeded that of the non-pregnant, while in one group no appreciable difference was found. The combined ratio, parturient to non-pregnant, expressed in terms of colonies, was approximately as 46 to 100.

D. *Comparison of Non-pregnant Women and Women Ten Days after Delivery at Term.*—Four groups of cases were investigated. In two groups the bactericidal power of the puerperal women exceeded that of the non-pregnant, while in two groups the reverse obtained. In none of the four groups was the difference marked, the combined ratio, puerperal to non-pregnant, expressed in terms of colonies, being approximately as 110 to 100.

E. *Comparison of Non-pregnant Women and Women Six Weeks after Delivery.*—Three groups of cases were investigated. In all three groups the bactericidal power of the late puerperal individuals slightly exceeded that of the others. The combined ratio, late puerperal to non-pregnant, expressed in terms of colonies, was approximately as 89 to 100.

F. *Comparison of Non-pregnant Women and Women Twelve Weeks after Delivery.*—In three groups of cases investigated no appreciable difference was observed in the bactericidal power of the one as compared with the other.

II. The Bactericidal Power of the Blood at Different Stages of Pregnancy (see Chart 2).

A complementary series of observations was made in which the blood of healthy parturient women, in labour or immediately after delivery, was compared with that of non-pregnant women and of women at or about the sixth month of pregnancy, the end of the eighth month, and at ten days, at six weeks, and at twelve weeks after delivery.

A. *Comparison of Women at Full Term and Non-pregnant Women.*—This group has already been considered (*vide supra*, C).

* The possibility that pregnancy might confer an enhanced degree of bactericidal power was suggested by a chance observation that in one of a series of six women investigated in the ante-natal out-patient department of the Royal Maternity Hospital the bactericidal power of the blood was markedly lower than that of the other women whose blood was tested; on this being subsequently examined showed that in this individual the abdominal enlargement was due to an ovarian tumour and not to pregnancy.

* *So far as our observations go, the effect of spontaneous uncomplicated labour on bactericidal activity is inconsiderable. The bactericidal power of fifteen healthy women at the commencement of labour was contrasted with that of a similar number at its conclusion. It was found that at the commencement of labour colonies were more numerous in eight and less numerous in six than at the time of delivery, while in one case no difference was observed. There is thus apparently a slight increase in bactericidal activity at the time of delivery as compared with the onset of labour, but the difference is not pronounced.*

B. *Comparison of Women at Full Term and at the Sixth Month of Pregnancy.*—Three groups of cases were investigated, each containing three women at full term and three at or about the sixth month of pregnancy. In each of the three groups the bactericidal power of the former exceeded that of the latter. The combined ratio, expressed in terms of colonies, six months to full term, was approximately 160 to 100.

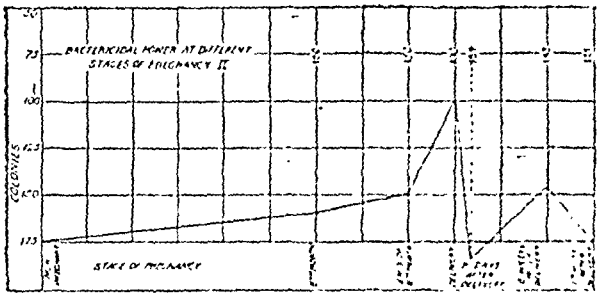

CHART 2.

C. *Comparison of Women at Full Term and at End of Eighth Month of Pregnancy.*—Seven groups of cases were investigated. In each of the seven groups the bactericidal power at full term exceeded that at the end of the eighth month; the combined ratio, expressed in terms of colonies, eighth month to full term, being approximately as 129 to 100.

D. *Comparison of Women at Full Term and at the Tenth Day after Delivery.*—Five groups of cases were investigated. In three groups the bactericidal power of the blood of women at full term considerably exceeded that of women ten days after delivery, while in two groups no appreciable difference was observed. The combined ratio, expressed in terms of colonies, ten days post partum to full term, was approximately as 184 to 100.

E. *Comparison of Women at Full Term and at the Sixth Week after Delivery.*—Three groups of cases were investigated. In two groups the bactericidal power at full term exceeded that of the late puerperium, while in one no appreciable difference was observed. The combined ratio, expressed in terms of colonies, six weeks post partum to full term, was as 143 to 100.

F. *Comparison of Blood of Women at Full Term and at the Twelfth Week after Delivery.*—Three groups of cases were investigated. The combined ratio, expressed in terms of colonies, twelve weeks post partum to full term, was as 175 to 100.

So far it is evident that in both pregnant and non-pregnant individuals there is considerable variation in the degree of bactericidal activity which the individual possesses. This variation is more marked during pregnancy and has a definite relationship to the period of gestation which has been reached. There appears to be a gradual increase in bactericidal activity as pregnancy advances which reaches its maximum at or about the full term of pregnancy. After labour there is a rapid decline in bactericidal power, the curve (see Charts 1 and 2) falling sharply, so that about the tenth day of the puerperium it reaches the non-pregnant level; thereafter there is a further temporary increase, which has disappeared by the twelfth week after *parturition*. In contrast to the views expressed by Bonney,[8] Douglas,[9] and others, a woman at the time of delivery appears to possess a degree of resisting power to infection considerably in excess of that of the non-pregnant individual. During the days which immediately follow delivery there is, however, a relative "negative phase" which may have an important application in the light of the serious character which a puerperal infection is liable to assume.

III. The Influence on Bactericidal Power of Parity and of such Conditions as Albuminuria, Prolonged Labour, Instrumental Delivery, and Severe Loss of Blood.

1. *Parity.*—So far as our observations go, there appears to be no difference in the degree of bactericidal power possessed by the parous as compared with the nulliparous non-pregnant individual; nor have we found any difference in this respect between the primigravid and the multigravid woman. In thirty-six groups of cases which were investigated it was found that the colonies which formed in the blood of primigravidae were more numerous than those in the blood of multigravidae in ten groups, and less numerous in eleven, while in fifteen groups no appreciable difference was observed. The more frequent occurrence of repair in primiparae than in multiparae is probably to be explained by the greater difficulty which generally attends a first labour rather than by any difference in resisting power to infection which the one class possesses as compared with the other.

2. *Albuminuria.*—The increased liability to infection which appears clinically to be associated with albuminuria and eclampsia prompted an investigation into the influence which this complication of pregnancy might exert on the bactericidal activity of the individual. In sixteen groups of cases the blood of a patient suffering from albuminuria or eclampsia was compared with that of healthy women advanced to the same stage of pregnancy; in eleven cases the bactericidal power of the albuminuric individual was below and in four cases above that of the others, while in one case no difference was observed. It would appear, accordingly, that albuminuric toxaemia tends to depress the resisting power to infection as measured in this way.

3. *Duration of Labour.*—In thirty groups of cases the bactericidal power of the blood was investigated in relation to the duration of labour, blood being withdrawn for examination at or about the time of delivery. For the purposes of analysis cases of difficult instrumental delivery were excluded. In each group the average duration of labour in the six cases making up the group was ascertained; the blood of those in whom the duration of labour exceeded the average was then compared with that of those in whom it was shorter than the average. In nineteen groups the bactericidal power was poorer in those women who had relatively long labours, in six groups the reverse obtained, while in the remaining five groups no appreciable difference was observed.

4. *Instrumental Delivery.*—In twelve groups of cases an attempt was made to determine the effect of instrumental delivery on the bactericidal power of the blood. Each group contained one or more cases in which the patient had been delivered by forceps, and in addition, for purposes of comparison, two or more cases in which delivery had been spontaneous. So far as was practicable blood was withdrawn within a few hours of delivery so as to minimize any modification in the bactericidal activity of the blood which might result from the introduction of infection. In ten of the twelve groups analysed it was found that the bactericidal power of those women who had been delivered by forceps was poorer than that of those delivered spontaneously, while in the remaining two groups this finding was reversed.

The above analysis of the effect of prolonged labour and of instrumental delivery (3 and 4) does not take into account the influence of such associated factors as fatigue, anaesthesia, or incidental obstetric complications, the effect of which it is difficult to appraise. It is illogical, accordingly, to interpret the findings just quoted as indicating that the resisting power to infection is necessarily affected either by the number of hours which a woman may pass in labour or by the forceps operation as such. All that seems reasonable to assume is that, apart from any question of the introduction of infection, a labour which is short and spontaneous will in general tend to react less injuriously on bactericidal activity than one which is tedious and instrumental.

5. *Severe Blood Loss.*—The number of cases in which it was possible to estimate the effect of severe blood loss on bactericidal power was restricted by the difficulty of excluding extraneous and, for the purposes of analysis, confusing factors in such conditions as ante-partum and post-partum haemorrhage, in which measures employed for the control of bleeding may of themselves modify bactericidal activity. So far, however, as an analysis has been possible it has conveyed the impression that with severe loss of blood a lowering of bactericidal power occurs.

Relationship of Bactericidal Activity to the Blood Elements and in Particular to the Leucocyte Count.

The observations of Payer,[10] Dietrich,[11] and others have shown that during pregnancy an increasing leucocytosis occurs, which reaches its maximum at the time of delivery and thereafter rapidly subsides. It was decided, accordingly, to examine the extent to which the modification in antibacterial activity which we have described could be related to the changes which occur in the blood elements, and in particular to the numerical increase in the white cells.

THE PUERPERAL MORBIDITY RATE IN PATIENTS DELIVERED NORMALLY.*

A COMPARISON BETWEEN CASES EXAMINED VAGINALLY AND CASES NOT SO EXAMINED, WITH REMARKS ON THE ADVANTAGES AND LIMITATIONS OF RECTAL EXAMINATION.

BY

A. M. CLAYE, M.D., F.R.C.S.,

TUTOR IN OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LEEDS.

MEDICAL students and pupil midwives at the Leeds Maternity Hospital have been taught for some years that vaginal examination during labour is a risky procedure, which should not be used except in certain indications. It was with a view to finding out whether this teaching was justified by the facts that I have investigated a series of 1,546 consecutive normal cases delivered in the hospital between August, 1926, and March, 1928, during which time I was the resident medical officer.

I have excluded from my normal category (1) all cases requiring intrauterine manipulation or instrumental assistance during labour; (2) all cases where there was any obvious predisposing cause of puerperal sepsis—for example, ante-partum and post-partum haemorrhage; (3) all cases of puerperal pyrexia, due to definite extragenital causes such as bronchitis, mastitis, phthisis, pneumonia, pyelitis, tonsillitis, etc. All cases with a perineal tear are classified separately to avoid confusing the issue.

A number of cases admitted from outside and subsequently delivered spontaneously without vaginal examination in the hospital are omitted, as, although they were almost certainly examined vaginally before admission, I have no sure information on the point. The morbidity rate in this class was abnormally high.

The normal cases remaining I have classified according to whether they were examined vaginally or not, and I have described the puerperium as either (1) morbid—by the Ministry of Health standard of puerperal pyrexia; (2) submorbid—where the temperature reached 99° or more at least twice during the twenty-one days following delivery; (3) normal—including apyrexial cases, cases where the temperature never reached 99°, and cases where the temperature reached or exceeded 99° on one occasion only. The temperature was taken in the axilla in all cases.

The vaginal examinations were done in almost all cases by pupil midwives under the supervision of the labour ward sister, in order to comply with the existing rule of the Central Midwives Board, which requires a pupil to perform a certain number of vaginal examinations before she can be signed up. It is a rule of the hospital that the labour ward sisters only perform abdominal and rectal examinations in their management of the normal cases.

The patient's vulva is shaved on admission and the external parts are cleaned with watery biniodide solution 1 in 1,000 before any vaginal examination is done, and also before delivery. The examiner wears gloves which have been boiled and steeped in biniodide solution.

The results of the investigation are rather what might have been expected. The morbidity rate of cases examined vaginally was almost twice that of cases examined only abdominally and rectally, and the morbid *plus* submorbid rate of cases examined vaginally was nearly one and a half times as great as that of those not so examined.

TABLE I.—*Cases Examined Vaginally* (309).

Number morbid	7 = 2.3	per cent.
Number submorbid	21 = 6.8	,,
Total morbid and submorbid	28 = 9.1	,,

TABLE II.—*Cases not Examined Vaginally* (778).

Number morbid	10 = 1.3	per cent.
Number submorbid	41 = 5.3	,,
Total morbid and submorbid	51 = 6.6	,,

The remainder of the 1,546 cases consisted of those with

1. *Parity.* In this class the morbidity was, again as be no difference between the primigravid by the parous as expected, still higher.

individual; nor have [illegible] North of England Obstetrical and Gynaecothirty-six groups of cases [illegible] found that the colonies which to.

TABLE III.—*Cases with Perineal Tears* (459).

Number morbid	12 = 2.6	per cent.
Number submorbid	50 = 10.9	,,
Total morbid and submorbid	62 = 13.5	,,

I quote the figures for forceps deliveries in the booked cases of the hospital over about the same period—that is, 1926, 1927, and 1928—to show how increasing the elements of vaginal examination and of trauma in a case increases still further the morbidity from sepsis. Of 199 cases, 21, or 10.6 per cent., were morbid from sepsis.

Presumably the increased morbidity in normal cases examined vaginally is not due, or at any rate not entirely due, to the introduction of organisms from outside by the examining finger, since this should be avoided by the precautions which are taken before a vaginal examination is made; it is probably due to the finger moving infected matter from a comparatively safe position in the vagina to a dangerous position within the cervix.

If it be accepted that vaginal examination during labour carries with it an increased risk of puerperal morbidity, I take it that we should avoid such vaginal examination when possible. In my view vaginal examination cannot be satisfactorily avoided in the following classes of case, and should be restricted to them:

1. Cases of ante-partum haemorrhage, however slight the loss, because of the importance of making an early diagnosis and establishing early treatment in cases of placenta praevia.

2. Cases where it is important to know the exact size of the os, and this cannot be gauged from the rectum; these are usually cases of breech presentation.

3. Cases where the doctor has been called in by a midwife or another doctor to a patient whom he has not seen before, where he cannot decide on the proper treatment without vaginal examination—for example, a case where there is some incompatibility between the head and the pelvis.

4. Cases where the doctor is about to resort to operative treatment—for example, before applying forceps or extracting a breech presentation.

In the remaining cases rectal examination is quite sufficient if any pelvic examination is necessary.

In cases seen at the ante-natal clinic where there is any question of incompatibility between the head and the pelvis, we avoid the necessity for making a vaginal examination during labour by examining the patient under anaesthesia at the thirty-sixth week and estimating, by Munro Kerr's method, the probability of the head passing through the pelvis undamaged at term; the diagonal conjugate is measured on the same occasion.

I now propose to amplify the statement already made that rectal examination, except in the four categories mentioned, is sufficient when a pelvic examination is necessary during labour.

Pelvic examination during labour is most usually undertaken to find out the amount of dilatation of the cervix, virtually all the other facts which it is desirable to know being ascertainable by abdominal examination. Any person of average intelligence who has had the necessary amount of experience can tell the size of the cervix by rectal examination, except in a very small proportion of cases. This small proportion is largely composed of breech presentations, where the consistency of the presenting part so closely resembles that of the cervix that it is not easy from the rectum to distinguish the one from the other; the same difficulty is encountered rarely in cases of head presentation where there is a large amount of caput.

Rectal examination can supplement abdominal examination in several other points of diagnosis. For example, if the membranes are intact their presence is no more difficult to recognize from the rectum than from the vagina. If the anterior tip of the cervix is oedematous, this can be felt from the rectum, though its treatment generally requires vaginal examination. Prolapse of the cord is another condition usually calling for treatment involving vaginal examination; in the majority of cases the cord appears at the vulva immediately after prolapse; if it does not it can be felt on rectal examination. Diagnosis of presentation can nearly always be made from the abdomen; but it is seldom possible to be sure of a

face presentation abdominally, while the diagnosis is easily made from the rectum as soon as the face is within reach of the examining finger; I have seen it so made by a pupil midwife on several occasions.

Let us consider the position of the midwife with regard to vaginal examination, in view of the four indications for it which I have already given.

1. If one of her patients bleeds ante partum, her duty is to summon medical aid; vaginal examination should be done, not by her, but by the doctor who is going to treat the patient.

2. If she has a case of breech presentation, she should again obtain medical aid. By the existing Central Midwives Board rules she is allowed to treat the uncomplicated breech, but who can be certain that a breech will be uncomplicated until delivery is in progress?

The third and fourth indications are not applicable to the midwife.

I therefore hold that it is not necessary for midwives to make vaginal examinations, and very desirable that they should be forbidden to do so.

Lastly, I should like to point out that if a doctor makes no vaginal examination on a given patient, and she subsequently develops puerperal sepsis, he can be quite clear in his own mind that he has not introduced the infection.

I am indebted to the honorary staff of the Leeds Maternity Hospital for their permission to make use of the records of cases under their care in compiling this paper, and particularly to Mr. William Gough for suggesting the investigation.

THE MICROSCOPICAL EXAMINATION OF MATERIAL CONTAINING FILTERABLE VIRUSES, AND THE LIMITS OF VISIBILITY.

BY

ALFRED C. COLES, M.D., D.Sc., M.R.C.P.LOND., F.R.S.ED.,

PHYSICIAN TO THE ROYAL NATIONAL SANATORIUM, AND CONSULTING PHYSICIAN, ROYAL VICTORIA HOSPITAL, BOURNEMOUTH.

THE term ultra-microscopic applied to the filter-passers seems somewhat unfortunate, and this expression, together with the idea that they could only be studied by means of ultra-violet photomicrography, and the erroneous idea of the limit of the ordinary microscope, is perhaps responsible for the meagre account of the actual appearance of some at least of these bodies.

THE EXTENT OF VISIBILITY WITH THE ORDINARY MICROSCOPE.

The size of a minute organism or particle that is visible with the microscope depends on several factors, amongst which are: the numerical aperture of the objective; the wave-length of the colour by which it is illuminated; the method of illumination, whether by transmitted, oblique, or dark ground; the refractive index of the medium in which it is mounted; and the depth of the stain. The numerical aperture (N.A.) of the objective and the wave-length of the colour used are by far the most important elements, and, speaking generally, the higher the N.A. and the shorter the wave-length of light the smaller the particle that can be seen.

In stained preparations the depth or the duration of the staining makes a very considerable difference in the apparent size of an object. For example, if a film containing *T. pallidum* be stained for only five minutes with Giemsa, and then examined dry, without a cover-glass, with an 8 mm. objective, using dark-ground illumination, it is possible to find a spirochaete. If this be examined with 1/12 inch oil immersion with ordinary illumination it will be very difficult to see the spirochaete, but when seen it will appear as the most delicate spiral that can be imagined. Let the film be stained for twelve or twenty-four hours, and the spirochaete will appear as a thick spiral cord. Even greater differences will be found in the apparent size of an object when faintly stained with one of the aniline dyes, when compared with one stained or impregnated with one of the flagella stains.

It is often stated in the literature dealing with filter-passers (Boycott, Martin, Cowdry) that organisms of the size of 0.2 or 0.25μ are "somewhat about the limit of direct microscopic vision" (Boycott[1]), and that anything smaller than that would be invisible with the highest powers of the microscope. But this is very far from being correct.

It would seem that the limit of *resolution* or separation has been confused with that of *visibility*, whereas they are totally different things. The resolution of an object glass is its power of dividing or separating a certain number of lines or dots to the inch, and our present limit of resolution of two lines or dots with ordinary light and axial illumination is generally given as 0.25μ, and for oblique light 0.2μ. The limit of visibility, or extinction limit, is the size of the smallest isolated dark particle that can be seen with transmitted light on a bright field with a given numerical aperture.

Whilst the limit of resolution with a lens of N.A. 1.4 is about 0.25μ, the limit of visibility of the same lens employed at full aperture would be considerably greater; and with this object glass, using white light, a dark isolated germ or particle just over 0.074μ in diameter will be visible, whilst with green light a germ just over 0.0673μ should be seen.

Mr. Edward Miles Nelson, who has devoted the whole of his life to the microscope, and who is undoubtedly the greatest authority on the subject, more than twenty years ago communicated a paper to the Royal Microscopical Society[2] "On the measurement of very minute microscopical objects." He states: "Briefly, then, the method is to bring the object just to the point of invisibility by reducing the W.A. (working aperture), and then the correction for antipoint will be the measure of the object." A full table of the values of the N.A. is given in the paper. I may add that one can determine the minimal visible of any objective by the following calculation: for white light of 43,000 waves per inch divide 1.041 by the N.A.; for green light of 50,000 waves per inch divide 0.942 by the N.A. of the object glass. These figures assume that the objective is used at its full aperture, and not, as is so commonly the case, by using, or rather degrading, say a 1/12 inch lens of N.A. 1.3 or 1.4 with an ordinary Abbé condenser.

Mr. Eliot Merlin, also a very great expert on both the microscope and telescope, has stated the case very clearly in *Watson's Microscope Record*, 1929, No. 17.

"The separating limit of any given N.A. should not be confused with its visibility limit for an isolated particle, such as a stained coccus viewed by transmitted light on a bright field. Unfortunately such confusion is common, it being frequently assumed that the minimum diameter of an isolated particle, or germ, observable under such conditions in the ordinary microscope must exceed about 0.25μ, this being really only slightly beyond the limit for an object glass of only N.A. 0.4 (that is, about that for a low-apertured cheap 1/2 inch objective) employed at its full working aperture in white light (5,607 wave-lengths), while the visibility limit for the same object glass with a screen (5,030 wave-lengths) is 0.236μ. That the separation and visibility limits are different can be quite easily demonstrated. Select on a virus preparation two cocci, the diameter of which happens to be about their distance apart. Reduce the aperture of the object glass until no interval between the two cocci can be detected. This is the *separation limit for that aperture for germs* or particles of similar diameter, but the joined-up pair of cocci will still be quite visible. Of course, it will be borne in mind that two distinct just-in-contact images of the two equal-sized (in reality well separated) cocci are being dealt with. It will require a considerable further reduction in the N.A. of the object glass to cause the images to completely fade away, which they will be found to do at a certain very definite aperture, this forming the visibility limit. Any selected single isolated coccus of accurately estimated (or otherwise measured) similar size will be found to exhibit a like visibility limit."

In an earlier number of the same journal[3] Mr. Merlin says:

"Apparently the difficulty of demonstrating living filter-passing cocci is in most cases merely due to their transparency in aqueous media, and not to their minute dimensions being beyond the diagram-defining power of the ordinary microscope. This difficulty is minute readily overcome by observing them on dark ground."

In conclusion he says:

"In the writer's opinion it is of paramount importance that neither a pathologist nor a bacteriologist should undertake true optical capacity of the ordinary microscope, for the very first time, unless furnished with ordinary glass and [illegible] matic object glasses, should [illegible] rated, this being the [illegible]

laboratory and technical workers all the world over. It cannot therefore be too emphatically maintained that it is an experimentally absolute fact that an object glass of 0.4 N.A. will, in white light of wave-length 45,300 per inch, just render visible a particle of 0.262μ in diameter; and similarly the 1/12 oil immersion of 1.30 N.A., in common laboratory use, should, if properly used to its full defining capacity, reveal particles of not less than 0.08μ diameter in white light, of 0.0724μ diameter with a screen wave-length of 50,000 per inch, and of 0.0571μ diameter with the photographic wave-length of 63,500 per inch.

Methods.

The material containing viruses that I have examined has been taken from the skin or mucous membranes—for example, herpes, vaccinia, etc. The part is well washed, dried, and then gently rubbed with a swab moistened with spirit. Vesicles and bullae, if present, are punctured, and in some cases the base is rubbed, and the resulting exudation, as free as possible from blood, is spread uniformly either on the cover-glass or more usually on the slide.

In the case of papules, etc., the cleansed surface is scraped with a sharp scalpel till some serum is present, just as one would do for the examination for *T. pallidum*. The film is usually exposed next to the vapour of iodine for about half a minute, allowed to dry in the air, and then fixed in alcohol for half an hour to an hour. In some cases the air-dried films are fixed in lucidol. They are subsequently stained in Giemsa all night, or from twenty-four to forty-eight hours, and the stain renewed once or twice. After washing, and when thoroughly dry, they are mounted in Gurr's mounting medium, in which less fading occurs than in any medium I know up till the present. Films are also made by the process of relief staining—that is, one drop of the serum and one drop of Indian ink, or a saturated aqueous solution of nigrosin, are thoroughly mixed with a needle, and the resulting mixture spread on the slide in as uniform a film as possible. The Indian ink I use is either Gunter Wagner's "chinchin" or "pelican," and the process is that well known as Burri's method. In the preparation of the commercial chinchin or pelican ink some workers recommend the addition of tincture of iodine, about one part to twenty-five parts of ink, and the mixture, after being well shaken, is allowed to stand for twenty-four hours, and then centrifuged. The German writers generally advise diluting the ink with five to ten times the amount of distilled water, centrifuging, and finally sterilizing the diluted ink.

Some time ago, after long experimenting with various methods of relief staining, I wrote an article, "Relief staining of bacteria, protozoa, infusoria,"[1] in which I stated that, after trying various methods, I came to the conclusion that nothing was equal to a saturated aqueous solution of nigrosin, which gives magnificent pictures of many flagellates and spirochaetes; but I now find, to my surprise, that the old Burri's Indian ink method gave much better results with the "virus bodies." I therefore look forward to any suggestions for improving the preparation of little use for diagnostic purposes, but when the organism is known no other method will give as fine an insight into the shape and external structure, but it must always be controlled by a stained preparation, and also by a film of the ink, or nigrosin alone, used as a control.

I am of opinion that any method of relief staining is of the ink, or a good substitute for it.

As to the microscopic outfit, I generally use Leitz 8 mm. 1/3 inch apo-objective of N.A. 0.65, and 1/10 inch. of N.A. 1.33, or 1/16 inch fluorite, and either Watson's paramatic dry or their holoscopic oil immersion condenser. In all cases I employ a green colour screen, generally Watten's No. 15 and 60 used together. For dark-ground illumination one of three methods is in use: (1) the paramatic condenser, used without oil, with a stop; (2) the holoscopic condenser, used with oil and a stop; and (3) Leitz dark-ground illuminator, with fixed stop.

I generally find that the ordinary paraffin lamp with half-[illegible] gives sufficient light, but for the most brilliant [illegible] effects nothing is as convenient or as cheap [illegible] small electric bulb of 60 candle-power, or the same candle-power, as first suggested by Mr. Nelson. Of course, these must be placed in a dark box, with only a small hole [illegible] at one side.

As a matter of fact, all the [illegible] filterable virus bodies that I have up to the present examined [illegible] are distinctly seen with the apochromatic 1/3 inch objective by dry dark-ground illumination, and this is the method I use in the first instance to determine whether these bodies are present, and, when present, in what part of the film they are most numerous or well defined.

General Microscopic Appearance of Bodies seen in Material Containing Viruses.

The bodies are Gram-negative, and they are not easily stained with any of the ordinary aniline dyes. With Giemsa they stain a red to reddish-violet colour, practically the same tint as most of the spirochaetes and many of the Rickettsia bodies. On microscopical examination exceedingly numerous minute granules of varying sizes, of unequal depth of stain, and generally of a round or an oval shape, are to be seen. They may roughly be recognized as having three or four different sizes. The largest are generally round, more rarely oval in form, and with Giemsa they stain a deep red-violet, much darker in colour than the smaller bodies. Their outline is not sharp like a coccus, but is somewhat ragged and ill defined. By careful focusing many of them seem to have a projection, tag, or spike, and in some a distinct, very fine flagellum-like structure can be seen. They are usually single, but not infrequently are attached or closely joined to one of the smaller bodies, which is, however, more faintly stained. Very seldom are the two larger bodies joined together like diplococci, but two, three, or four may be arranged in a straight or curved line at considerable distance apart, and they are apparently connected to one another by a very delicate thread; but this is difficult to see in Giemsa-stained films. The smaller types stain less deeply and more reddish in colour, are generally much more numerous, but not nearly as conspicuous as the larger bodies. They may be arranged singly, in pairs, or in short chains. All the virus bodies appear more deeply stained when they are seen lying over some stained background than when seen in a clear space. Their most characteristic features are: their inequality in size, their arrangement in loosely connected chains made up of bodies of unequal size, unequal density of stain, unequal distance apart, and, if they are oval in shape, the long axis may lie at a different angle from the rest.

If the preparation be examined by dark-ground illumination, by any of the methods previously described, they will be quite easily seen, shining brilliantly as very definite and distinct golden grains, of unequal size and somewhat irregular arrangement, often lying two, three, or more in a chain. Indian ink preparations—made as described—show them, in parts at least, extremely well. The inequality in size, the arrangement, and the spiked or flagella-like projections, and at times the very delicate filaments connecting two, three, or more bodies in loose irregular chains, are much more easily made out than in stained films. Relief staining with nigrosin is inferior to the Indian ink for these particular minute structures; the larger bodies are well seen, but the smaller ones seem to be somewhat lost in the stain, and are not at all conspicuous objects.

In 1922 Mr. Nelson first noticed the flagellum-like structure on the "virus bodies" of vaccinia, and says "it is the smallest germ on which I have seen a flagellum, and in spite of their smallness these were not at all difficult to see; the medium-sized germs measure about 0.3μ by my extinction method."

Later in the same year he writes: "The vaccine virus germs are not isolated, but are fixed to a very delicate mycelium, just like tubers on a rhizome." Mr. Eliot Merlin a little later confirmed both these findings. I was able to see the flagella-like processes on many of these bodies. (By the by, it is still a little uncertain whether the filter-passers possess the power of motion, or whether what is seen is merely Brownian movement. The majority of observers incline to the latter theory.)

I could not distinctly make out the connecting threads, at least not convincingly, and I was at that time of opinion that what these skilled observers had seen were merely very delicate fibrin filaments underlying these bodies. Only quite recently in films made from herpes labialis with Indian ink have I abundantly satisfied myself of the existence of these very delicate threads.

The existence or not of these connecting filamentous structures might be regarded as merely of academic interest, but I think that if the bodies I have described are indeed the virus, their presence might explain one of the peculiar attributes of the virus—that is, their marked difficulty, in some cases at least, of passing through the pores of a filter.

My friend Mr. Eliot Merlin has very kindly examined stained preparations of many virus bodies which I have submitted for his opinion. I here add his quite independent view of the appearance and size of some of them.

"It appears to me that the 'virus bodies' only differ from ordinary cocci in point of smallness and variations in size.

"*Shape.*—Some of the larger bodies are markedly oval, but *most of the average and smaller-sized germs appear quite round.* Deeply stained Giemsa forms, large and small, appear well defined in most cases. Some exhibit a projecting knob, and a few have apparent flagella, but not much attention has been given to the search for flagella.

"*Size.*—Observation has been mainly concentrated on accurately measuring the diameter of the large and small forms. A seeming peculiarity of 'virus bodies' is their numerous graduation in size.

"On the slide of *herpes labialis*, stained Giemsa, measurements of the virus bodies on a bright field show:

	Diameter.
Largest bodies	0.63μ
Large bodies	0.75μ
Numerous average bodies	0.52μ
Small bodies	0.3μ
Smaller bodies	0.26μ
Smallest, but quite numerous, grade ...	0.21μ

"The measurement of the germs has been carefully done and may be relied upon within small limits of error. The probable error is within a trifling amount (say less than one unit), in the second decimal place of a micron. Thus there are, in this preparation, about six well-marked grades of size easily seen, and *well within the visibility capacity of an 8 mm. objective of N.A. 0.65.*

"*Vaccine virus.*—Here are my measurements for this:

Large bodies	0.8μ
Medium, numerous common size, same as herpes labialis	0.52μ
Small	0.44μ
Smaller	0.32μ
Smallest	0.26-0.21μ

"Practically the vaccine virus germs are about the same in variations of size as the herpes.

"By the way, re shape. All bodies so small that their diameter would be beyond the separation limit of the N.A. employed would be imaged as round, *even if really square or oblong.* Thus a germ that is imaged as square-shaped, such as a tetraspore, must be truly so shaped, and therefore within the resolving (separating) limit of the optical combination employed. But a minute germ imaged as round *may* be any shape—square, triangular, or oval—should its diameter happen to be below the resolving limit of the N.A. available to reveal its true shape."

The following is a list of the morbid conditions in which I have found definite "virus bodies": vaccinia, varicella, herpes labialis, herpes zoster, pemphigus, psoriasis, lichen planus, dermatitis herpetiformis, verruca plana, conjunctivitis, influenza, and the common cold. There is little to be said about any of these conditions.

The influenza bodies were found associated with pneumococci in films made from the lung of a child, and my experience is in agreement with Mervyn Gordon, that the bodies met with were coccoid rather than bacilloid. The only obscure case was that of chronic conjunctivitis, the film being sent me by my friend Dr. Maddox.

The association of herpes zoster and varicella is always of interest, and I have seen a case of an adult with typical herpes over the right shoulder, in whom within a few days an equally typical attack of varicella occurred.

What are the criteria which suggest that the small bodies seen with the microscope are indeed the viruses? It is not easy to answer this question definitely, but after the eye has been accustomed to the appearance of these minute organisms—say in a film of vaccine—there is little difficulty with other specimens. Their small size, the faintness and colour of the staining reaction, the occurrence in enormous numbers, the numerous gradations in size, the arrangement in two, three, or more at long and often irregular distances, and their connexion in some cases by very fine filaments, are together very suggestive, and, as experience is gained, diagnostic. As Arkwright[3] says

"The differentiation of colloid particles of about 0.2μ in size by means of the microscope is often extremely difficult, and requires attention, especially to their arrangement and the range of size and shape, rather than to the appearance of individual particles."

I have examined very many controls, such as fluid from blister, the exudation from many cases of dermatitis, etc., but I have not found anything like these minute yet definite bodies. My impressions seem to indicate that they are fairly easily recognizable in films from the skin or mucous membrane in the diseases mentioned and known to be due to filterable viruses, but I should not expect to detect them in films of the peripheral blood.

The next obvious question is, Can you differentiate the virus bodies of one disease from those of another? At present I should say this was very difficult, and in many wellnigh impossible, but I put the problem to Mr. Merlin, who writes:

"*Herpes Zoster.*—The germs are rather markedly of one uniform size, measuring 0.35μ, many being diplococci, but some also single.

"*Conjunctivitis.*—Resembles vaccine virus, size of germs varying, large forms rather plentiful; medium-sized forms measure 0.35μ.

"*Influenza* (from lung).—Quite typical virus-like vaccine, consisting of many grades in size. Medium forms 0.3μ.

"*Lichen Planus.*—Varying grades of size, but the largest forms in this preparation that are numerous only run at about 0.52μ, while the medium small equal about 0.3μ.

"*Common Cold.*—Typical range of size, large forms seemingly more numerous than smaller grades. Medium small 0.35μ.

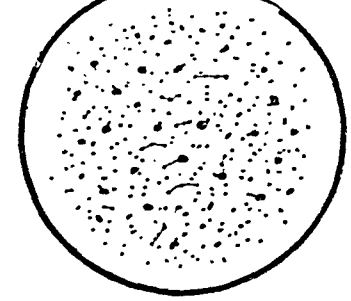
"*Varicella.*—Medium-sized bodies numerous at 0.3μ, and so greatly preponderate as to perhaps constitute a feature by which this virus can be recognized.

"In reply to your query as to whether any of the virus bodies could be distinguished from each other, I certainly think, with practice at least, some of the preparations exhibit sufficiently marked differences, such as uniformity of size of bodies. In some large bodies are numerous, in others not.

"Then, too, the exceptionally numerous large bodies in the cold slide serve to distinguish this virus from the others, whilst on the varicella slide the very numerous 0.3μ forms might serve a like purpose."

So far I have only had an opportunity of examining fairly common filter-passing diseases, but our experience of these leads me to think that the statement made by Martin, that "he preferred to consider the dimensions were not of the small order suggested by some observers," as being very near the truth.

I should very much like to be able to examine preparations of other diseases due to filter-passers, such as variola, molluscum contagiosa, dengue, etc. Films could easily be made from variola, molluscum, and the vesicles of foot-and-mouth disease, and I should be most grateful if those working on any of these diseases would be kind enough, as opportunity occurred, to forward me air-dried films from any of these.



Diagrammatic sketch showing appearances of the virus bodies.

What part ultra-violet photography will play in the further elucidation of virus diseases remains to be seen, but I am mindful of a statement made to me some time ago by a great microscopist and scientist. He said that laboratory microscopists remain unchanged from the old days when they commonly used an oil immersion objective to show objects quite within the range of dry lenses. So now may it not be that ultra-violet light is sometimes considered necessary when the ordinary microscope is really fairly adequate?

I have taken sixteen photomicrographs at a magnification of 1,500 diameters of ten different virus bodies on one quarter-plate, but am afraid this hardly lends itself to reproduction. I have therefore made a very diagrammatic drawing of the general appearance of these minute bodies (see figure).

I take this opportunity of expressing my very great thanks to Mr. Eliot Merlin who, though he is not a pathologist but a bacteriologist, is [illegible] at the microscope, for his very valuable help he has given me.

YELLOW FEVER: PRELIMINARY NOTE.

I have had the opportunity, since the above was written, of examining films containing the virus of yellow fever. Dr. Edward Hindle, whose very successful work with this dangerous disease is well known, kindly sent me films of the blood, liver, and spleen from four rhesus monkeys infected with yellow fever, and later blood films from one bitten by infected mosquitos, from the first to the last day of illness. I would here express my heartiest thanks to Dr. Hindle.

In these films, when stained with Giemsa, I have found certain minute bodies which closely correspond with those I have already described from other filterable diseases. On microscopic examination a large number of very faintly stained bodies were found lying in the space between the tissue cells or corpuscles. At first glance they were regarded as probably minute precipitates of stain, but on closer and more prolonged examination they were found to have definite form and shape. In the majority of cases they were minute round or oval bodies, stained a faint red colour with Giemsa, irregularly arranged, of somewhat unequal size, and unequal depth of stain. Most of them were single, many arranged in pairs, and a few in lines. The individual particle may have a distinct flagellum-like process, others have a bud- or spike-like projection, giving the organism the appearance of a comma. Rarely filaments are seen connecting two, three, or four together, as was noted in other virus diseases.

These minute bodies were never found in dense groups or compact clumps as one so commonly sees in the Rickettsias, but they were fairly equally distributed in the blood serum. They were very numerous in the liver and spleen, but were fewer though quite distinctive in the blood. It was particularly noticed that many of them were in pairs, like minute diplococci—or, as I call them, diplogloboid bodies—and in the blood I regarded these as especially suggestive. When examined with dark-ground illumination these minute bodies shone out very brilliantly.

Mr. Merlin, who has confirmed these findings, has kindly taken the following measurements. In the liver and spleen their size varied from 0.9μ to 0.17μ; intermediate sizes being 0.39, 0.28, and 0.22μ. The average size of the most numerous form was about 0.3 to 0.25μ. In the blood faintly stained bodies varied from 0.5 to 0.17μ; the other grades being 0.3, 0.24, and 0.17μ in diameter.

"The variations in size," Mr. Merlin remarks, "approximate to the bodies in the vaccinia virus, except that the smallest in the latter only reached 0.21μ, whilst in the yellow fever preparations the most minute are 0.17μ or even slightly less in diameter."

The question naturally arises, What are these bodies, and with what may they be confused? They are quite easily seen with 1/3 inch objective and dark-ground illumination, and are very fairly uniformly distributed in all parts of the films in which the corpuscles are not too close together. They could not, in my opinion, be confused with the contents of cells, or the granules from a neutrophile leucocyte which has been ruptured in spreading; but it may be very difficult to differentiate them from debris from stain.

All the filter-passing bodies that I have examined require fairly deep staining with Giemsa to render them at all conspicuous, and prolonged staining with Giemsa tends to the production of some debris, however carefully it is carried out.

In films of vaccinia, etc., we have to deal with almost a pure culture of the virus bodies, whilst yellow fever is the first disease in which I have looked for such bodies in the blood or organs. Notwithstanding these difficulties I am of opinion, after spending considerable time on the examination of them, that these very minute bodies, with such definite characteristics, are not artefacts or debris from stain. I have made controls by spreading films of normal blood on the same slides, and subjecting them to precisely the same fixing and staining.

I think it will be found that these bodies, if not the virus, may have some connexion with it.

DISTEMPER IN DOGS.

Sir Charles Martin and Professor J. C. G. Ledingham kindly sent me some unstained films labelled "distemper," and a piece of spleen from distemper in dog. I found in the former, and, after staining films from the spleen, in the latter, bodies which were very like those previously described. They were very numerous in films made from the spleen. They were on the whole somewhat smaller than those met with in vaccinia.

Much further work, however, must be undertaken before one can definitely express an opinion on the exact nature of such minute bodies.

A CASE OF CARDIAC SYPHILIS WITH VENTRICULAR ANEURYSMS.

BY

HAROLD COOKSON, M.D., B.Sc., M.R.C.P.,

CLINICAL ASSISTANT, NATIONAL HEART HOSPITAL; LATE MEDICAL REGISTRAR, MIDDLESEX HOSPITAL.

An unusual cardiac condition, the result of syphilitic processes, is here recorded.

The patient, a woman of 43, was admitted to University College Hospital in April, 1927, with a history of breathlessness on exertion for two years, epigastric pain on exertion for three months, and oedema of the legs for five days. A diagnosis of aortic syphilis with aortic incompetence was made. An electro-cardiogram taken at this time is reproduced in Fig. 1; it shows normal rhythm,

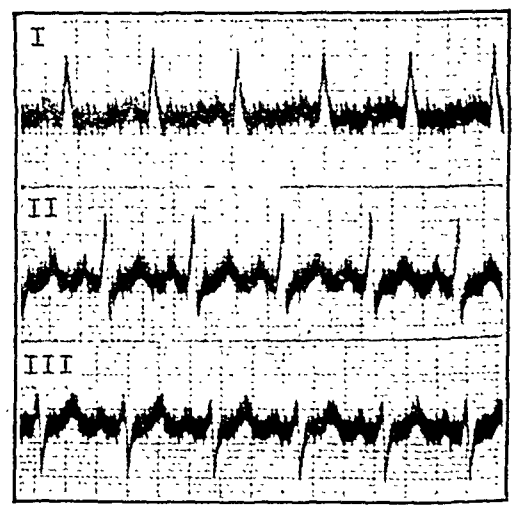

FIG. 1.—Time marks = 1/5 sec.

sinus tachycardia, slight left ventricular predominance, and the T wave just negative in lead 1. The patient was treated with anti-syphilitic drugs (sulfarsenol, novarsenobillon, bismuth, and iodides) for one month, and was discharged considerably improved.

Four months later she was admitted to the Middlesex Hospital in a very distressed condition. She was orthopnoeic, cyanosed, and had oedema of the feet; she complained of epigastric pain, and vomited continuously. Sino-auricular rhythm with many extra-systoles was present, the rate being about 70. The heart was enlarged (apex beat in the fifth space five inches from the middle line); no murmurs were audible. Shortly after admission auricular fibrillation occurred, the ventricular rate being at first about 140. This was reduced by digitalis in the course of three days to 100, but the patient's condition got worse; vomiting was more frequent, and epigastric pain was still complained of. Death occurred suddenly five days after admission, while the patient was trying to defaecate.

The post-mortem findings were as follows (Bland-Sutton Institute of Pathology): The heart weighed 19 oz., and in

the pericardial sac were 19 oz. of straw-coloured fluid. The parietal layer of pericardium was adherent to the left lung, and the visceral layer was covered with organized fibrin, especially at the base of the heart. The myocardium was pale and slightly softened. Three cavities, or aneurysmal dilatations (Fig. 2), occupied the posterior part of the base of the left ventricle; their diameters were 1½, 1/2, and 1/2 in. Their ventricular surface was covered with rough injected granulation tissue; externally they were covered by the area of greatest pericardial thickening. On section the walls of the aneurysms were found to consist of fibrous tissue containing considerable deposits of calcium. All the valves were normal. The aorta showed only very slight atheroma, and the coronary arteries were patent except for a branch of the circumflex division of the left coronary, which was obstructed as it crossed one of the aneurysmal pouches. The other organs showed chronic venous congestion only. Microscopic section of the aneurysmal walls showed necrotic tissue bounded by dense fibrous tissue, the last infiltrated with plasma cells and lymphocytes, the plasma cells predominating. The vessels surrounding the degenerated area showed marked obliterative changes, and in some cases the lumen was occluded.

FIG. 2.—Showing the left ventricle opened. The anterior wall has been reflected to the left; the three aneurysms lie in the posterior wall at the base. The wall of the lowest pouch has been incised to show layers of calcified tissue.

Comment.

Aneurysm of the ventricle is not an uncommon finding; it nearly always follows cardiac infarction resulting from atheroma and thrombosis of the coronary arteries. Syphilitic aneurysms of the ventricle are rare. The site of election for an aneurysm which is the result of an infarct is at or near the apex of the left ventricle; syphilitic aneurysm of the ventricle, judging from the few cases published, seems to be commoner near the base. Morris[1] records one occupying the same site as those in the case herewith described. McFie and Ingram[2] relate the case of a native boy of the Gold Coast who fell dead; he had two aneurysms near the apex of the left ventricle, one of which had ruptured; in the interventricular septum just below the aortic valve was a mass of 10 mm. diameter, which appeared macroscopically and microscopically to be a gumma; it is presumed that the aneurysms were of syphilitic origin. A similar heart in which a gumma and an aneurysm were found is recorded by Young[3]; the aneurysm was at the base of the left ventricle.

In the present case the walls of the aneurysms were composed of fibrous tissue of great thickness and density, and in them were considerable deposits of calcium. It must be concluded, therefore, that the condition had been present for a long time—probably many years. During this time a slow replacement of muscle tissue would be taking place with the gradual development of heart failure. The pericardial effusion was no doubt the last straw which increased the cardiac burden beyond endurance.

I am indebted to Sir Thomas Lewis for the electro-cardiogram, and for details of the patient's condition when in University College Hospital; and to Dr. G. E. Beaumont for permission to use the findings when she was admitted under him at the Middlesex Hospital.

THE PROBLEMS PRESENTED BY SCHOOL PREVENTIVE MEDICINE IN RURAL AREAS.*

BY

A. C. T. PERKINS, *M.C.*, M.D., D.P.H.,

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH, WEST SUFFOLK COUNTY COUNCIL.

THE problems presented by school preventive medicine in rural areas, though not differing fundamentally from those arising in urban districts, are to a large extent modified owing to the scattered nature of a country population. Moreover, solutions which have been found satisfactory in large centres of population are in many cases totally impracticable when applied to country districts.

The district dealt with in this study is a typical rural area in which about 75 per cent. of the population are engaged in agricultural pursuits, and live for the most part in scattered villages and hamlets. The population at the census of 1921 was returned as 108,982, with a density of approximately 250 per square mile as compared with 588 for England and Wales as a whole. In the whole of the administrative county there are only four towns with a population exceeding 3,000. Leaving out these four towns, there are left in the rural areas proper approximately 9,392 children distributed in 139 village schools, making an average attendance of 67 per school.

The medical staff concerned in administering the county school medical service consists of a school medical officer, who is also county medical officer of health, one assistant school medical officer, one dental surgeon, one dental attendant, and four school nurses. All of these officers are whole-time and also employed in other public health duties in the county. This staff, as I shall show, is totally inadequate for the work which confronts it, but nevertheless it probably represents a fair average of that which is to be found in any similar district. No use is made of private practitioners in respect of the school medical service, though their services are to some extent made use of in other departments of the county's public health activities.

Two medical inspections are carried out at each school yearly. The first of these is the routine inspection, at which the age groups laid down by the Board of Education are examined. In addition, those children marked for "re-inspection" are also seen. These are children in whom some defect requiring treatment or observation has been noted at a previous inspection. At the second visit these "re-inspections" are again reviewed.

Whenever a defect requiring treatment is found, except in such minor conditions as impetigo, etc., the initial

* This paper is an abridgement of the winning essay submitted in competition for the Hempson Prize of the British Medical Association, 1929.

procedure is always the same. The parents are informed verbally or by notice of the defect found and urged to call in their family doctor. If at a subsequent inspection it is found that treatment has not been obtained, further pressure is brought to bear, the *modus operandi* differing according to the circumstances of the case. It is our invariable practice, in nearly all cases, to urge that the necessary treatment be carried out through the family doctor. Nevertheless, experience has shown that the number of cases actually obtaining treatment in this way constitutes a very small percentage of the whole. For this state of affairs there are various reasons. In the first place the local doctor may himself prefer treatment to be carried out under one or other of the county schemes. For example, comparatively few general practitioners are prepared to deal with errors of refraction. Secondly, we have to cope with the almost invariable reluctance of the parents themselves to call in medical aid before a child is obviously ill. In my experience this applies even when a child is a juvenile member of one or other of the approved societies. Even where there is frank illness the family doctor is often not called until late in its course, if at all. In nearly every case I have found that poverty is the explanation of a reluctance to consult the family doctor. A tremendous amount of work is carried out by private doctors in this district every day for which they know only too well they are likely to receive little or no return. But even so, many cases escape attention because of a certain sturdy independence which refuses to call in aid for which it knows it cannot pay. Where it is possible for definite illness to go unattended in this way it is small wonder that less alarming conditions such as anaemia, malnutrition, or "nerves" are not regarded with the gravity which they truly deserve. In urban districts, where an ailing child can be kept under more or less frequent observation, the onset of more serious trouble may be detected and dealt with early, but in a rural area like this the biannual visits of the school medical officer are, in many cases, quite useless from a preventive point of view.

A partial solution of the difficulty lies in the extension of the Insurance Acts to cover the dependants of insured persons. A workable scheme of this nature would ensure a great deal of potential chronic disease being checked in its early stages, and also considerably facilitate co-operation between private practitioners and the school medical service. On the other hand, the financial aspect of such a scheme is formidable in the extreme, and it would need the greatest consideration and circumspection to formulate a practicable working arrangement.

A problem, more grave because less susceptible of solution, is that arising in connexion with *cases of defect not diagnosed at medical inspection*. Actually, in my experience, in a large number of cases requiring active treatment this is shelved because, as will be shown, inadequate facilities for "following up" result in a failure to arrive at a definite diagnosis. An examination of the figures showing the distribution of defects found to require treatment in this area during 1927 is illuminating.

Return of Defects (excluding Uncleanliness and Dental Diseases) found by Routine Medical Inspection to require Treatment in 1927.

By far the majority of these defects do not come within the realm of general medicine. They consist chiefly of defects suitable for treatment at minor ailment clinics—for example, minor skin complaints—or conditions calling for some form of specialist treatment—for example, defective sight or enlarged tonsils and adenoids. We all know, however, that such defects do not, in practice, constitute the bulk or even a large proportion of the morbid conditions which, in childhood, are found to require treatment. To take a concrete example, rheumatic diseases of the heart, and many other manifestations of chronic rheumatism, have their inception in acute or subacute conditions occurring in childhood. In London it has been computed that 25 per cent. of chronic invalidity in children is due to rheumatism.[1] In rural districts, where a child has frequently to walk long distances in inclement weather, with no adequate provision for drying clothes at school or for a suitable midday meal, conditions predisposing to rheumatism are even more prevalent than in towns. Yet the records for this area show that comparatively few defects definitely attributable to rheumatism have been noted. No case of organic heart disease requiring treatment was diagnosed during 1927, though there were 104 cases of abnormality recorded as requiring observation. Chorea was not recorded in a single instance, while "growing pains" were only noted in a few cases accompanying more gross lesions such as enlarged tonsils. It is fundamentally improbable that juvenile rheumatism in this county is as rare as these figures would suggest. It is more likely that in the hurly-burly of a routine medical inspection minor manifestations of rheumatism have been, in the past, entirely missed. Careful observations made by the writer during the year 1928 on this specific point suggest that not less than 2 to 3 per cent. of all children are definitely rheumatic, though the complete figures are not yet available.

The lack of due recognition accorded to rheumatic manifestations throws into relief the comparative superficiality of much of the work done at school medical inspections. In my opinion, this is largely due to the lack of any proper means of following the minor degrees of defect found at school inspections down to their real place of origin *in the home*. It is a point easily lost sight of that while, for reasons of convenience, inspection of children takes place in school, yet some five-sixths of a child's life, even in term-time, is spent outside the school precincts. It is in the home, in the street, in the field, that defects have their origin—not in the comparatively hygienic environment of the school. If it is to be truly preventive in its functions school medicine must follow the *early* defect back to its origin in the home.

When every allowance has been made for inherited predisposition to disease it still has to be admitted that faulty hygiene, in some form or other, is the match which sets ablaze the ready-laid faggots we call a diathesis. It is the duty of school medicine first, on the preventive side, to extinguish the match; secondly, on the curative side, so to drench the faggots of predisposition that they are no longer combustible.

Under the present system it is only the more severe degrees of defect which are followed up, and this, indeed, fully occupies the available time of the existing medical staff. Minor degrees of defect are merely recorded, and then forgotten until the child comes up for the next *routine* inspection three to five years later. This is a grave fault. Any defect, however slight, indicates a morbid process already at work. Before the child is next seen the invader may have become too firmly entrenched to be easily ejected. A defect inevitably points to some faulty hygienic factor in the environment, and it is only while it is still slight in degree that rectification of the faulty factor will result in a cure of the defect. *To investigate the environment we must go from the school into the home.*

Every practitioner is familiar with the type of child who is quite obviously physically unfit, and yet in whom systematic examination reveals no morbid condition to which a definite label can be attached. We call the condition debility, slight anaemia, "nerves" (the common parental diagnosis), and so on. These are merely symptoms, and in most cases definite disease is not revealed even by the most careful examination. But all symptoms must have causes, and if we write down the cause in this type of case as "faulty home hygiene" we shall usually be not far wrong.

It is, however, rarely possible at the school to detect the precise factor in the home environment which is at fault. I have found inquiries in this direction especially difficult owing to the fact that the parents of a child are frequently absent at the time of inspection; this is largely due to the parents living at a distance from the school, indifference, etc. Accordingly one has not even the advantage of being able, by questioning the parents, to obtain reliable information as to the home environment. I have found that the only practicable method of investigating the home conditions is to send a school nurse to make a personal visit to the parents. Unfortunately I have found it quite impossible, in practice, for the present staff of school nurses, with numerous other public health duties to perform, to make more than a mere start upon the immense amount of work waiting to be carried out in this connexion. Apart from the preliminary inquiries, many "following-up" visits are required in order to ensure that the environmental faults detected are being satisfactorily corrected. In order to carry out the necessary work adequately a total of not more than 1,500 pupils per *full-time* school nurse has been suggested for urban districts.[2] In a rural area this would need further reduction, and a figure nearer 1,000 would be more reasonable. This would entail, in this district, a staff of twelve *full-time* against the present staff of four *part-time* nurses.

If it be admitted that most of the defects found in children of school age actually originate in the home, our focus is at once shifted to the pre-school child. In 1927, excluding uncleanliness and dental defects, 4.7 per cent. of entrants were found to require treatment, compared with 5.5 per cent. and 5.02 for leavers and intermediates respectively. Moreover, I have found that most children requiring treatment at a later age have usually possessed a slighter degree of defect as entrants.

It is useless to tackle the environment of the school child if he is left to pass his pre-school years unheeded. The toddler requires a periodical medical inspection and subsequent following up by a nurse even more urgently than his bigger brothers at school. Unfortunately there is at present in rural districts no adequate machinery for carrying out such examinations. Mothers cannot usually even if willing, bring their younger children long distances to a child welfare clinic. In this county we have only nine such clinics. I have found that while these are well patronized by parents living close at hand, children are not brought to them from any considerable distance. To derive real benefit from child welfare clinics in a rural district it is essential to establish one in practically every village throughout the area. Such a large number of clinics could only be staffed adequately by utilizing the services of local practitioners on a very much bigger scale than at present.

In the case of the pre-school child this would offer definite advantages. The child could be seen at more frequent intervals. The local practitioner has usually an intimate knowledge of the previous and family history of each child, and parents are probably more willing to bring their children to be examined by the family doctor than by a comparative stranger from the public health department. Finally, "following up" would be easier, since the local practitioner is constantly in and out of the homes in his district. In this county I have found that the child welfare centres conducted by a local practitioner go with a distinctly greater "swing" than do those for which the whole-time staff of the public health department are responsible.

The importance of preventive work in the pre-school years cannot be overestimated. Most of the defects which I find at school inspections can be traced back to the toddling age, and could have been prevented by adequate medical supervision during that critical period. Sir George Newman has remarked on the fact that "year by year there is a steady stream of defect or physical impairment of the entrants coming into the schools . . . apparently never lessening, which requires medical or surgical treatment."[3] My experience in a scattered rural district suggests that this deplorable condition is due largely to a system which, ignoring the vague imponderable signs of a faulty environment, takes cognizance of it only when its inevitable results have become established. Such a system may avoid a certain amount of permanent crippling; it cannot be termed truly preventive. The stream of defect by the time it reaches the school has become too large to be mopped up, like a puddle, without leaving a trace. It must be followed back, and that without delay, to be stemmed at its source in the home during the pre-school years.

The disposal of exceptional children is another big problem which faces the school medical service in rural areas. By the term "exceptional children" is to be understood those children suffering from a defect of such a nature as to preclude their deriving the maximum benefit from instruction in an ordinary elementary school. There are in this county 392 such children, including 16 children totally or partially blind or deaf, 84 mental defectives, 7 epileptics, 65 cases of active tuberculosis of all types, 122 crippled children (including orthopaedic defects and those with severe heart disease), and 95 cases classed as merely "delicate"—for example, pre- or latent tuberculosis, malnutrition, anaemia, etc. Of these children 332, or 84.8 per cent., attend ordinary elementary schools. They are scattered over the district—one, two, or three in each school. In existing circumstances it is impossible to organize them into special classes, where they might receive the attention and instruction best suited to their individual needs. The only alternative at present is to send them to suitable residential special schools. Unfortunately to carry out such a scheme for any considerable portion of the exceptional children in this area has been found to present practically insuperable difficulties. The annual cost of maintaining a child in a residential school is about £80. If every exceptional child in this county were thus dealt with, the annual cost would be about £25,000, or ten times the present total expenditure on school medical services. Further, the benefit to the child (and ultimately to the community at large), especially in the case of mental defectives, has not been found commensurate with the expenditure involved. Moreover, it is often impossible to obtain parental consent to the removal of children suffering from only a moderate degree of defect. Finally, the accommodation available at residential special schools is still so limited that it is often difficult to secure admission for any given case.

The disposal of exceptional children is a problem largely peculiar to rural areas. In urban districts it is easy to provide non-residential special schools or classes within a

reasonable distance of children's homes. In London 6,282 out of a total of 6,307 mental defectives are attending certified special schools or other institutions.[4] To attain a similar result in this district it would be necessary to provide a number of special classes sufficiently accessible for all those children suitable for them. For approximately 400 children the total number of such classes could hardly exceed about thirty in all. Scattered over the county, they would be so separated that it would be impossible for children to attend without providing some means of mechanical transport. This is obviously not an economic proposition, since it would involve sending a vehicle daily to each village solely to pick up one or two children.

In venturing to suggest a tentative solution of the grave difficulties I have detailed, I approach my task with some diffidence, for I have no personal experience of the practicability of such a scheme as I am about to suggest, nor do I know of any other district where a similar scheme is already in operation.

Shortly, I suggest the total abolition of the present numerous small village schools and their replacement by a small number of large central schools, each providing accommodation for at least 1,000 pupils. Children from outlying villages could then be brought in by motor buses, run by the county council. The whole of the children attending an average village school could easily be accommodated in a single bus of modern type. Two buses would be ample to transport all the children at even the largest of the village schools. Leaving a convenient central point at a fixed time daily, the bus could easily stop at one or two points *en route* to pick up children who at present have to walk long distances to school from outlying hamlets. This would be of immense benefit to many young children who at present reach home at the end of the day tired out and often soaked to the skin. The expense of providing this transport could be partly covered by allowing some or all of the buses to run as public conveyances during the hours between and after the school journeys.

A scheme of this magnitude, like Rome, could not be built up into existence in a day, but it is not Utopian. The advantages of central schools are already recognized by the Board of Education on quite general grounds. In this county small steps towards centralization have already been made. During the last two years five village schools have been entirely closed, and transport has been provided to convey the children attending them to the nearest large school. This movement is likely to increase more rapidly in the near future.

With the establishment of central schools the exceptional children problem solves itself. Instead of one or two such children in each school there would be forty or more. Such a number would make feasible the establishment of special classes. Three such classes, of about fifteen children each, would be a convenient number in the average central school. One would provide for the older mentally defective or seriously backward children; one for the younger, and one for older physically defectives. In fairly small classes of this nature children could have just that individual attention which is necessary if they are to derive the maximum amount of benefit from their instruction. Within wide limits the disadvantage of mixing children of different educational standards would be offset by the individual instruction received.

I have referred in some detail to this exceptional children problem because it is one which is incapable of any solution under the system of elementary education at present practically universal in rural areas. But the advantages offered to the school medical service by central schools by no means end with the disposal of exceptional children. I will briefly outline some of the directions in which my experience suggests that the provision of central schools would greatly facilitate and even augment the work done in other branches of school medicine.

Provision is made for the treatment of certain specified classes of defect under a scheme of the education authority, notably defects of vision, dental defects, and certain minor ailments. Some of these are dealt with by local practitioners or dentists, but something like four-fifths are treated directly under the county schemes. Owing to the fact that inadequate transport facilities make it impossible for most children to attend at a central clinic, nearly the whole of the refraction and dental work has to be carried out at the schools themselves. The dental surgeon, or myself, arrives at a school where there are children to be treated, perhaps only two or three in all, equipped with all the necessary impedimenta for the work in hand. It is not difficult to imagine the degree of disorganization in the ordinary school routine entailed by our visit. Many of these village schools consist of a single room, and few of them have more than two, so that, practically speaking, the school has to be more or less cleared. If it is raining and the children cannot be turned into the playground, the difficulties of all concerned are increased tenfold. I have vivid memories of hours spent in cramped quarters, doing refractions in darkened lobbies, provided with no form of artificial heating even in mid-winter, and surrounded by the wet, malodorous hats and coats of the scholars. In such circumstances it is astonishing what satisfactory results are obtained, but the waste of time entailed in the repeated packing, unpacking, and inter-school travelling is immense.

The arrangements for treating minor ailments are even more chaotic. The conditions dealt with include minor skin diseases—impetigo, for example—and such small injuries as bruises and slight cuts, with miscellaneous defects such as chilblains, and so on. Usually all that can be done is to give directions for their treatment to the parents and head teacher, relying for skilled supervision on such comparatively infrequent visits as the school nurse (who may have forty or more widely separated schools in her district) is able to pay. It is probable that much work coming under the head of minor ailments which at present is referred to the local doctor would, if better facilities were available, be dealt with under the county scheme. This is usually work which, as Dr. Alfred Cox has pointed out,[5] the private practitioner would prefer to be without, since it entails an amount of trouble quite incommensurate with the recompense likely to be obtained.

With the advent of the central school all this wasteful expenditure of time and energy could be obviated. It would be easy enough to provide suitable accommodation at the school itself for all the work of the school doctor and nurse. Reduced to essentials, two rooms would suffice. There should be a nurse's room, equipped for the efficient treatment of the various minor ailments, and a doctor's room, which could easily be arranged to be suitable for purposes of both inspection and treatment. In respect of minor ailments, it would be easy enough for the school nurse to visit each central school in her district at a fixed hour daily and attend personally to the treatment of all children requiring it. If the present number of school nurses were augmented to the figure suggested earlier in this essay, each school would have its own individual and full-time nurse.

The school nurse could also carry out another invaluable service which at present is not attempted at all. Teachers often present to me children concerning whom they wish for one reason or another to have a skilled opinion. Under our present system it is often months before a chance comes for a child to be thus presented. If a school nurse were in attendance daily, teachers could present children about whom they were worried for a preliminary "screening." The nurse, who in this as in most areas is a highly trained individual, would be quite competent to advise as to the best mode of procedure in each case. Some she would be able to advise or treat herself. In others—probably the majority—she would advise the services of the family doctor to be sought, and from such a source there would be more likelihood of the advice being followed than if it came from the teacher. The remaining cases would be referred for special examination by the school doctor at his next visit. These visits would take place at least once a fortnight at each school, instead of, as at present, two or three times a year. Thus there is no reason why a child should not receive medical attention within a short time of anything wrong being noticed. In addition, the more frequent attendances of doctor and nurse would make it much easier than at present to follow up vigorously any special case, and to ensure that adequate treatment was obtained without delay.

A further argument for abolishing the present village schools lies in the extremely unsatisfactory sanitary conditions obtaining in the majority. Many are old and built without that provision for satisfactory lighting and ventilation which modern research has shown to be necessary for health. Heating, in nearly all cases, is by open grate or slow combustion stove, which makes for bad distribution and insufficiency. In many schools there is no supply of water fit for drinking purposes, and in the majority the closet and urinal accommodation is inadequate and correspondingly insanitary. At no school is there any special arrangement for the drying of children's clothing and boots. In this connexion I would cite the report of the chief medical officer to the Board of Education for 1925.[6] The sanitary condition of most of the schools in this area is as bad as, if not worse than, any of the instances there quoted. Rectification of these conditions, in view of the local circumstances of isolated country villages, would be in many respects quite impracticable, and in any case would impose upon the managers a much greater expense than could reasonably be insisted upon. It would probably be a more economic proposition to close unsatisfactory schools as rapidly as circumstances permit, transferring the pupils to suitable central schools.

I do not wish to suggest that the expenditure which would be involved in the establishment of central schools would be justified in the interests of the school medical service alone. As a matter of fact, if these schools were built on an open-air pavilion system, leaving ample space for expansion as circumstances required, the initial outlay would not be nearly so great as at first sight would appear. In any case the demands of school preventive medicine do appear to me to offer strong support to any arguments in favour of establishing central schools on more general educational grounds. My attention was first drawn to the possibilities of such schools from a medical point of view by numerous conversations with head teachers throughout the county; these I have found to be, almost without exception, strongly in favour of such a move on quite general grounds, both of economy in administration and as the best means of attaining a higher standard of elementary education in rural areas. Of these wider considerations I am, of course, not entitled to speak with authority, but my experience leads me to believe that they do in fact exist, and provide a thorough justification for urging the claims of the school medical service to a share in the benefits that the central school has to offer.

In conclusion, I would reiterate what I have endeavoured to show earlier in this study—namely, that in all cases even a slight departure from the normal and healthy condition has its origin in a faulty environment. Sometimes that faulty environment may be found in the school, but far more often it is to be found in the home, where, after all, the child passes the greater part of its early and adolescent years. More and more are we beginning to realize the importance of the pre-school years to the future history of the individual. In the proper direction of those critical years the local practitioner might be granted a very much larger share than he has been offered in the past.

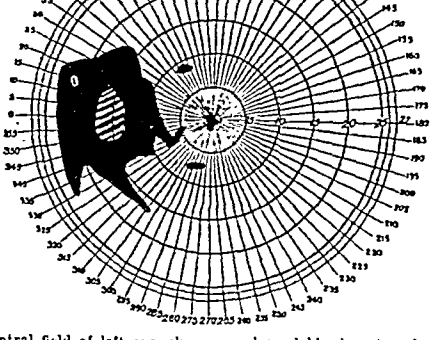
Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

OPTIC NEURITIS AND DENTAL SEPSIS.

On November 21st, 1928, a man consulted me because for three days previously he had been conscious of "a black cloud" in the outer field of his left eye; there was no gross field defect. He had one dioptre of hypermetropia with slight astigmatism. The vision in each eye with correction was normal (6/6). There was no central scotoma. Young's "threshold" test (a very delicate one) for light difference was negative. The macula was unaffected, but the nasal edge of the left optic disc was "fluffy." So far, then, there was nothing much to be found abnormal beyond his consciousness of a cloud in his left field; but a definitely described symptom is a quarry always worth pursuing.



Central field of left eye, showing enlarged blind spot and scotomata. The cross-hatched area represents the normal size of the blind spot of Mariotte.

On examination of his central field with the Elliot scotometer the blind spot of Mariotte was found to be much enlarged, with snail-track extensions towards the fixation point and one or two isolated scotomata (see diagram). The average normal blind spot is marked by cross-hatchings for comparison. This, in conjunction with the hazy nerve-head, pointed to optic neuritis. It was evidently not of the usual toxic type met with in tobacco and some other poisonings, where the *papillo-macular bundle of nerve fibres* is affected first, and macular vision with colour impairment is a very early symptom.

The patient, a watchmaker, aged 35, was a non-smoker, the urine was free from sugar and albumin, and syphilis could be virtually excluded. His breath was foul, and examination by a laryngologist showed a tonsil with stale secretion in one of the crypts; this was evacuated. Five days later the vision had fallen from 6/6 to 6/12, and there was slight loss of central colour perception. I then had his teeth examined radiologically, although they appeared sound to the eye except for some pyorrhœa of the lower incisors. He had root fillings in two upper bicuspids; the film showed probable septic trouble at the apices of these teeth. His dentist extracted them both, finding a broken-down granuloma at the root of one; he also extracted the lower incisors.

On December 4th vision in the left eye had now improved to 6/9 partly. The relative central scotoma was still present. His next visit to me was on January 25th, seven weeks later, during which time his mouth had been dealt with antiseptically. His vision was now 6/6 easily, and there was no central scotoma. The blind-spot enlargement and the two small scotomata had disappeared; he had lost the consciousness of a cloud, and the optic disc had resumed its normal appearance. He had made a complete recovery, and has regained much better general health.

I think there is no doubt that the optic neuritis was due to the apical dental sepsis, and that the patient's resistance was impaired by absorption from the septic tonsil and from the pyorrhœa.

At a time when there is a tendency to a reaction from the wholesale removal of teeth on *x*-ray findings it is well to remember that where an important organ such as the eye is in jeopardy, and search for other causes has failed, a suspicious tooth should be sacrificed without hesitation.

I should like here to emphasize the great value of the Elliot scotometer, which is, of course, only a very quick and convenient means of applying Bjerrum's test. The enlargement of the blind spot and the two small scotomata would be entirely missed by the ordinary perimeter. A 2-millimetre white object is used at a metre distance, and the central field up to 25 degrees is, as it were, magnified.

The slight haziness at the nasal edge of the disc was not obviously pathological; and, with normal vision and no central scotoma, had I not found confirmatory evidence of its significance by means of the scotometer, I might on his first visit have missed it altogether. A second opportunity, when the diagnosis was obvious, might not have been afforded me, to the detriment of the patient and the discredit of our specialty.

Sydney, Australia. E. TEMPLE SMITH, F.R.C.S.Ed.

PERFORATION OF A GASTRIC ULCER IN A SEPTUAGENARIAN.

THE following case of perforation of a chronic gastric ulcer is worth recording in view of the age of the patient and the long history of illness.

Miss X, aged 70, was admitted in a collapsed state to the Seamen's Hospital, Tilbury, on May 9th. Her pulse rate was 136, temperature 98.4° F., and respiration rate 28; her tongue was furred and she had an anxious expression. On examination it was noted that the abdomen did not move on respiration; it was acutely tender all over, especially in the epigastrium, and of board-like rigidity. Liver dullness was present and the flanks were dull on percussion.

History.—On the previous night the patient, while in bed, was suddenly seized with violent abdominal pain and difficulty in breathing. The pain was severe and continuous, and had not abated when she was admitted to hospital. She vomited some mucus. There had been a slight action of the bowels during the same morning. Her past history suggested that she had had a chronic gastric ulcer for at least thirty-two years; she had had severe haematemesis thirty-two years ago, and during the whole period up to the present had suffered from pain and vomiting after food, with periods of remission lasting several months during which she was quite well. There had been a recurrence of haematemesis sixteen years ago.

Operation.—On opening the abdomen I found the peritoneal cavity full of serous fluid, with flakes of lymph over the stomach and intestines. There was a perforation the size of a sixpenny-piece high up on the lesser curvature, which appeared previously to have been adherent to the under surface of the liver. The pylorus and duodenum were normal. Having closed the perforation with chromic catgut sutures and sutured the omentum over it, I placed a drainage tube in the pelvis and left it in for thirty-six hours. Towards the end of the operation the patient's condition gave rise to some anxiety, and on her return to the ward she was given saline subcutaneously. She made a perfect recovery and was discharged a fortnight later.

Perforation of gastric ulcer in a patient aged 70 is very rare, other points of interest in this case being the thirty-two years' history of ulcer, and the fact that recovery took place though operation was not undertaken till eighteen hours after the occurrence of perforation.

Medical Superintendent, Seamen's Hospital, Tilbury.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

DEPTFORD DIVISION.

AT a meeting of the Deptford Division of the British Medical Association, held on June 19th at the Erith District Hospital, Dr. GEOFFREY BOURNE delivered an address on some clinical aspects of cardiac pain.

Dr. Bourne began by reminding his audience that William Heberden was the first physician to describe accurately the type of pain now known as cardiac, and to associate it definitely with disease of the heart. This he did in a paper read to the Royal College of Physicians in 1768. He then referred to the "danger belonging to it," the "sense of strangling and anxiety," and called it angina pectoris. Jenner, visiting Hunter at Bath, wrote to Heberden and predicted that disease of the coronary arteries would be found ultimately, a view which was confirmed at the autopsy. Physiologically speaking, continued the lecturer, pain stimuli could arise in or near the heart from the pericardium, from the adventitia of the cardiac vessels, and from the first part of the aorta; the myocardium itself was insensitive to trauma. The impulses so arising passed through the cardiac ganglia, thence to the three left cervical ganglia, and finally, by way of the rami communicantes of the last cervical and upper five dorsal segments, into the spinal cord. The common conditions clinically associated with cardiac pain were true angina pectoris, coronary thrombosis, coronary sclerosis, and pseudo-angina. In coronary thrombosis there was usually present some previous coronary disease, due to arterio-sclerosis or syphilis. A thrombosis most frequently occurred in the branches of the left coronary artery, often in the distribution of the anterior septal branch, and near the apex. If large it was followed by rupture of the heart and death; if small, it might become healed and leave little but scar tissue behind; if intermediate, there remained some impairment of cardiac effort. The event was often preceded by the symptoms of coronary sclerosis. The onset was sudden, with pain, fever, and leucocytosis. Cardiac function was impaired and a pericardial rub would emerge after a few days if the lesion was severe. The pain was like that of angina, but was not relieved by amyl nitrite; it was not pericardial, for it was immediate and sudden, whereas the friction, if it appeared, was later. The fever was often masked by the associated shock, and the temperature should therefore be taken in the rectum. The blood pressure, which might well have been taken at some previous time, would be found to be much lowered. The prognosis was worse if fever was high, leucocytosis considerable, and friction and cardiac irregularities were present. Recurrence was always possible. In making a diagnosis it was important to differentiate true angina and acute abdominal conditions. Electro-cardiographic tracings were characteristic.

True angina, said Dr. Bourne, was that serious, often fatal, condition which was characterized by four criteria: the patient was seized in an attack, often with no exact relation to exercise; he was unable to move; he feared that he might die; and relief was often obtained by amyl nitrite. The heart muscle and the coronary vessels were usually diseased. Disease of both or either might be absent, in which case disease of the aorta was often present. The condition was to be differentiated from coronary sclerosis where the pain was not severe, there was no fear of death, and there was a relationship between the pain and the amount of exercise taken. Allbutt's theory was that the pain was due to over-distension of the aorta, and that death was by inhibition through the depressor nerve and the vagus. But angina was not relieved by atropine, and there were no vagal endings in the ventricular muscle. Mackenzie's theory was that the pain was due to muscular exhaustion. But conditions which showed acute and chronic generalized cardiac failure to the greatest extent—namely, acute rheumatism, diphtheria, and chronic congestive mitral failure with fibrillation—were remarkably free from cardiac pain. Was it not therefore possible, suggested the lecturer, that the pain was due to local differences in ventricular function, the result of local physical tension or chemical variation, rather than to some generally acting cause? Attempts had recently been made to alleviate the severe attacks of pain. Surgery, on the whole, was disappointing, but alcohol injection of the affected nerve roots had been practised with success, at first by Mandl, latterly by others. Of White's five most severe cases two were completely relieved, two had no more severe attacks, and one was unchanged. Relief had now lasted for nine months. There was no danger in the proceeding. The patients most suitable were those in whom pain was very severe, so that life became burdensome, and those who had a relatively healthy myocardium.

The pain of coronary sclerosis, continued Dr. Bourne, had the same distribution as true angina. Its onset was gradual, and after a definite amount of work, which was pretty constant in the individual, it disappeared on resting, and there was no fear of death. In all respects it resembled the pain of intermittent claudication. It appeared to be associated with a hardening and narrowing of a coronary vessel. In treating the patient it was important to relieve him of the suspicion that he might have "angina." As much exercise should be allowed as would not produce pain. Lactose was useful in the diet. Theobromine sodium salicylate was of value in many cases in doses of 7½ to 20 grains, three times a day, after food.

Reports of Societies.

THE SCIENTIFIC STUDY OF INEBRIETY.

AT the meeting of the Society for the Study of Inebriety on July 9th a brief presidential address, which resolved itself into a series of questions, was delivered by Mr. W. MCADAM ECCLES, entitled "Some gaps in the study of inebriety."

Dealing first with alcohol and the vascular system, Mr. McAdam Eccles asked what was the exact action of varying percentages of circulating ethylic alcohol in the blood. Was there any effect upon the blood plasma itself? Had alcohol any direct action upon the delicate cellular tissue composing the walls of the arteries when they became, it might be said, bathed in a dilute alcoholic solution? Was arterio-sclerosis definitely more common in inimoderate than in moderate drinkers of alcoholic beverages? Was the absence of development of arterio-sclerosis in total abstainers one of the reasons why their expected mortality was so markedly lower than that of moderate drinkers? Further, was there any actual effect of alcohol upon the innervation of the muscular tissue in the blood-vessel wall? With regard to the heart, again some pertinent questions might be asked. Did the alcohol circulating in the blood passing through the heart affect more than the endocardium, possibly by reaching even the muscular tissue? What was the actual cause of the fatty degeneration of the heart in even moderate drinkers? Alcohol might have much to do with upsetting the finely adjusted heart muscle. Was it of the nature of a true peripheral neuritis affecting the cardiac innervation? Why was there quickening of the rate of the heart's beat? Was it interference with inhibition, or was it a "stimulation"? Turning to alcohol and the central nervous mechanism, the speaker asked, What was delirium tremens? No decisive answer was given in the textbooks. Was this delirium due to ethylic alcohol circulating in the blood, or to some other constituent of the favoured alcoholic beverage, or to some chemical substance—a toxin—produced somewhere in the body? Much research work was desirable on the actual effects of alcohol on the excretion of urine. What caused the increase of flow after the drinking of alcohol? How soon after a glass of champagne could alcohol be detected in the urine, and for how long after such a quantity had been drunk could traces of alcohol be observed in the urine excreted? Some of these gaps in knowledge urgently required filling, and the fact that they remained gaps did not redound to the credit of our fine body of investigators. The public, and many medical practitioners, were still living with the ideas of the past century, and it was for that society to make definite pronouncements and thus to create public opinion. Mr. McAdam Eccles hoped that his year of office as president might not be unproductive of a right form of "stimulation" in this respect.

Methylated Spirits and Impure Forms of Alcohol.

Sir WILLIAM WILLCOX then gave an address, illustrated by specimens of various alcohols, on the toxic effects of methylated spirits and impure forms of alcohol. He said that methylated spirit was first introduced in 1858. When it was found that people were drinking methylated spirit, which was a spirit diluted with wood naphtha, the composition of methylated spirit was altered, and certain small percentages of piridine and paraffin were added. The commercial methylated spirit of to-day was a noxious fluid: it not only caused poisoning if taken internally, but its application externally to the body was dangerous also. It had been so much altered in order to make it non-potable that its use in industry was somewhat hampered. The Government had met the case by introducing another form of methylated spirit, which was sold under great restrictions—an industrial methylated spirit, which was 90 per cent. alcohol mixed with only 5 per cent. of wood naphtha, instead of 10 per cent. as in the days before the war. Therefore industrial methylated spirit was poorer than the pre-war methylated spirit, and the wood naphtha also was itself poorer, he believed, than in the past. Surgical spirit was industrial methylated spirit to which had been added some substances to make it more unsuitable for drinking purposes—namely, 2½ per cent. of castor oil and 1 per cent. of boric acid. It was extremely unlikely that ordinary methylated or denatured spirit would be used by anyone as a beverage, though the industrial spirit might be so used. There had been a great many recorded cases of methylated spirit drinking. In 1926, it was stated, 2,000 deaths had occurred in America from this cause. In Scotland, in 1922, methylated spirit drinking became so prevalent as to necessitate the passing of strict regulations. Sir William Willcox said that he had seen cases of addiction when the spirit consisted simply of alcohol and wood naphtha, but not of addiction to the new composition. Of the evil effects which followed methylated spirit drinking the most notable was blindness, which was frequently permanent. Yet he was not aware of a single recorded case of blindness in this country due to methylated spirit drinking. But the fact that at least 5 per cent. of the cases of optic atrophy seen at the ophthalmic hospitals were due to undiscovered causes was significant, and it seemed possible that methylated spirit or methyl alcohol had not been investigated as a possible cause. In the United States every package of methylated spirit containing less than five gallons was marked by a skull and crossbones, and on the label was the following: "Complete denatured alcohol is a violent poison. It cannot be applied externally to the human or animal tissues without serious injuries resulting. It cannot be taken internally without inducing blindness and general physical decay, ultimately resulting in death." Thus was medical knowledge conveyed to the American public. It was the impure forms of alcohol which were the most dangerous. When the term "alcohol" was used in the popular sense, what was meant was ethyl alcohol (C_2H_5OH), but there were several other kinds of alcohol, some of which, like methyl alcohol, were offered or sought as substitutes. Purified methyl alcohol had a remarkable effect on the body. The symptoms following ordinary alcohol consumption (ethyl alcohol) came on within an hour, but with methyl alcohol they were delayed for several hours. The preparation produced much irritation to the stomach, with pain and vomiting; also intense headache, drowsiness, and coma; the last of these might persist for several days, differing again from the effects of ethyl alcohol, after indulgence in which the patient never remained unconscious for more than twenty-four hours. Methyl alcohol was much more poisonous than the ethylic form, its fatal dose being from one to two ounces. The substance was very slowly excreted, and could be smelt in the breath for a week after imbibition. Methyl alcohol had been used in many countries as a substitute for ethyl alcohol; the preparations containing it were the most dangerous things in the world. In America methyl alcohol was sold under deceptive names, such as "Colonial spirit" or "Eagle spirit," "or "essences" of this or that. It had been used for adulterating whiskey, brandy, sherry, rum, and even cider. In Germany there had been two serious epidemics of methyl alcohol poisoning from an adulteration of brandy with it. Finally, Sir William Willcox mentioned some other forms of alcohol, which, however, did not come to the same extent into the picture as possible resources of the addict. Propyl alcohol (C_3H_7OH) was not very unpleasant to the nose, and it could be used to some extent to replace ethyl alcohol in medicine. It was about twice as poisonous as ethyl alcohol, and induced a somnolent and drowsy condition. It also, on being drunk, produced a large quantity of acetone in the body. Its permanent effects were no more harmful than those of ordinary alcohol. Amyl alcohol ($C_5H_{11}OH$) was five times as poisonous as ordinary alcohol; it caused vomiting, intense headache, and drowsiness.

Sir William Willcox mentioned the case of a brilliant young man on a mission in America, who at a New York hotel was brought a bottle of some spirit by a waiter, and took a glass reluctantly on the pressure of a friend. As a result he went blind, though he later recovered his sight, a central scotoma remained, and this so depressed him that eventually mental degeneration supervened and he died.

NEUROLOGY AND PSYCHOPATHOLOGY.

JELIFFE and WHITE'S *Diseases of the Nervous System*[1] has come to occupy an important position in the libraries of all neurologists, and indeed of very many general practitioners who take a keen interest in neurology and psychiatry. The authors, more particularly Jeliffe, are of an encyclopaedic turn of mind, and the fifth edition of their book shows us to what an extraordinary extent they are conversant with the most recent advances in the literature of their work. At the same time they are careful to stress, some may say unduly so, their own attitude towards neuro-psychiatric problems. The section dealing with the vegetative nervous system and with the endocrinopathies has been extensively revised and brought up to date. It is the best account in English of this difficult department of neurology at the present moment. In the chapter dealing with neurosyphilis, the authors wisely lay stress on the fact that meningo-vascular neurosyphilis and parenchymatous neurosyphilis are not always differentiated; the former is usually very amenable to treatment, the latter much less so; this is an important distinction. The account of the treatment of general paralysis to our mind leaves a great deal to be desired. No results of malarial treatment are given, although large numbers are available in the literature, and treatment by means of tryparsamide is not mentioned. It is in Part Three, devoted to what the authors call the "psychical or symbolic systems," that most fault will be found by English psychiatrists. Here the psycho-analytic viewpoint is given too much rein, and many hypothetical and nebulous concepts are allowed to take the place of the more solid ground on which modern psychiatry has been built. An extensive account of epilepsy from a psycho-analytic viewpoint is given, but in the discussion of therapeutic measures we find no results of the treatment of epilepsy on psycho-analytic principles. These criticisms, however, apply only to a small portion of the book, and, considering the ground covered, the authors are to be congratulated on a worthy presentation of a very wide and difficult subject.

In the eighteenth volume of *Nouveau Traité de Médecine*,[2] which is devoted to the general symptomatology of the pathology of the nervous system, the editors, Drs. ROGER, TEISSIER, and the late Professor WIDAL, have given us a typical presentation of the French school of thought in neurology. The chapter on aphasia by Foix is the best in the book; eighty pages are devoted to it. Foix gives a good description of the time-honoured sensory and motor aphasia of Wernicke and Broca. The illustrations to this chapter are very pleasing. It seems a pity, however that the views of Henry Head should be dismissed in a paltry twelve lines, and that the views of Henschen, who has devoted such a busy life largely to the study of aphasia, should receive even less—to wit, five lines. In the chapter dealing with disorders of pronunciation and elocution we find stuttering defined as clonic convulsive dysphasia, and stammering as tonic convulsive dysphasia; these may sound rather lengthy definitions, but they are undoubtedly useful. The chapters on tremors and contractures by Haskovec, the Prague neurologist, are particularly good; the photographs and diagrams of gait are excellent. Foix and Chavany provide us with sixty pages on the reflexes, and cover the ground very thoroughly, introducing electromyograms of the knee-jerks, etc. Mme Dejerine and Gauckler deal with the sensory disturbances in great detail, accompanying their article with a wealth of excellent diagrams. This chapter competes strongly with the one on aphasia for first place in order of merit. The last few chapters deal with the eye, the ear—a particularly good chapter—and the cerebro-spinal fluid. Mental diseases are dismissed in seventy pages. Looking back on the book as a whole we are struck by the predominantly French tone of it; there is little attempt to discuss the views of others, though in fairness we must admit that this failing is not confined to the fellow-countrymen of Duchenne, Charcot, and Pierre Marie.

ASHHURST'S "SURGERY."

THE third edition of ASHHURST'S *Surgery, its Principles and Practice*,[3] bears a somewhat close resemblance in its general arrangement and get-up to another well-known textbook representing the views of the Philadelphian school of American surgeons—namely, Da Costa's *Surgery*. Ashhurst's *Surgery* is a general textbook for the use, primarily, of the student, and by including chapters on orthopaedics, venereal diseases, and gynaecology it covers the field in a comprehensive manner. The subject-matter is clearly written and reasonably condensed, and while the proportionate space devoted to the less common diseases is perhaps greater than that in most English textbooks, it cannot be suggested that too much space has been thus used. The English student would do well to supplement his reading by reference to such a book as this, which will broaden his surgical outlook and make his ideas of treatment less insular.

Modern methods of treatment and diagnosis are well represented and, like most American productions, the book is copiously and well illustrated, including fifteen plates in colour. Even the smaller illustrations are clear, and, with the exception of a few radiograms which have lost so much of their definition as to render them almost useless, none may be considered redundant. A small point of great value is the inclusion of a reference to the authority (name of author and date of publication) for all special statements made throughout the book. There are many hundreds of such references, which are quite up to date, and are rendered still more useful by a complete index of authors. There is little to be adversely criticized in Ashhurst's *Surgery*, but we feel that, in view of modern tendencies, a little more attention should have been devoted to radiotherapy with gamma rays. Without losing sight of the fact that the author of a standard textbook has to be reasonably cautious in his attitude to innovations, there can be no doubt that the student ignorant of the beneficial effects of gamma rays on certain types of neoplasm, and of the fact that in some clinics gamma irradiation has replaced excisional surgery in their treatment, cannot be considered properly equipped to advise his patients. The quotation with which the author prefaces his book is very relevant in this particular respect: "Les moyens chirurgicaux sont directs et quelquefois terribles" (Vidal de Cassis). We hope that the defect to which we have drawn attention may be remedied in the next edition, so that an excellent book may achieve its author's aspiration, expressed in the first edition, "to afford a true perspective—providing a source of information which shall indicate where further knowledge is to be found—giving clear and accurate statements and setting the facts definitely before the student."

CUTI-VACCINATION IN TUBERCULOSIS.

Is it creditable to scientific medicine that after forty years the position of tuberculin as a therapeutic agent is still undecided? This question is raised again by the publication of a monograph by Dr. J. DEKKER on local immunization against tuberculosis by the cutaneous route.[4] In a preface to the book Professor BESREDKA tells how one morning a serious young enthusiast presented himself at the Pasteur Institute in Paris, full of the success which had attended his treatment of patients in his country district. He was advised to continue his observations, and to publish nothing until he had obtained further proofs of the efficacy of his treatment. Dr. Dekker died while still young, but under the aegis of Professor

[4] *Immunisation Locale contre la Tuberculose par Voie Cutanée.* Par J. Dekker. Preface de A. Besredka. Amsterdam: H. J. Paris. 1928. (Med. 8vo, pp. viii + 104; 17 plates. 7s. 6d.)

Besredka his observations in one hundred cases are now submitted to the judgement of clinicians, together with his views on the mode of action of tuberculin given by the method of cuti-vaccination.

In developing his treatment Dr. Dekker followed the lead of Dr. W. Poundorf, who, while not the first to practise cuti-vaccination, introduced simple technique into the procedure. Dr. Dekker used two vaccines: A, a mixture of tuberculin and of an emulsion of dead bacilli; and B, the same as A with the addition of anti-staphylococcic, anti-streptococcic, anti-pneumococcic, and anti-influenzal vaccines. He scarified the skin of the patient so as to reach the endothelio-reticular layer, causing a drop or two of blood to appear. As a rule 32 to 40 scarifications were made, each eight centimetres long, and into these six drops of the vaccine were rubbed. Except in acute cases, dangerous to life, in which immediate large doses were necessary, a preliminary test vaccination was made. This consisted of five scarifications, one centimetre long, into which one drop of vaccine was rubbed. This procedure, however, seemed to be of no prognostic value, since, according to Dr. Dekker, excellent results had followed treatment when the skin reaction was entirely negative. Moreover, in more than five hundred treatments undertaken he never saw a focal reaction lead to an increase of focal or general disease.
